Arenadata DB

Arenadata DB (ADB) is a distributed analytical data storage built on the open-source massively parallel system Greengage DB and designed to store and process large amounts of structured and semi-structured data (up to tens of petabytes).

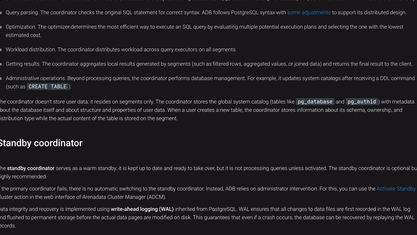
Arenadata DB (ADB) is a Massively Parallel Processing (MPP) database based on Greenplum DB.

The MPP architecture consists of a cluster of simultaneously operating nodes. ADB implements this as a cluster of separate PostgreSQL instances.

ADB uses the shared-nothing approach where each segment has its own portion of data. Multiple segments can run on a single host, but they process data independently. The system primarily scales horizontally by adding more physical nodes to the cluster.

The ADB architecture consists of three core components:

- Coordinator
- Standby coordinator
- Segments



ADB architecture

Coordinator

Coordinator (formerly master) is the entry point to the database. End users connect to the coordinator to submit queries.

The coordinator functions include:

- Client authentication. The coordinator controls client access to the system using the standard *pg_hba.conf* file. Segments accept SQL client connections from the coordinator only.
- Query parsing. The coordinator checks the original SQL statement for correct syntax. ADB follows PostgreSQL syntax with some adjustments to support its distributed design.
- Optimization. The optimizer determines the most efficient way to execute an SQL query by evaluating multiple potential execution plans and selecting the one with the lowest estimated cost.
- Workload distribution. The coordinator distributes workload across query executors on all segments.
- Getting results. The coordinator aggregates local results generated by segments (such as filtered rows, aggregated values, or joined data) and returns the final result to the client.
- Administrative operations. Beyond processing queries, the coordinator performs database management. For example, it updates system catalogs after receiving a DDL command (such as `CREATE TABLE`).

The coordinator doesn't store user data; it resides on segments only. The coordinator stores the global catalog (tables like `pg_database` and `pg_authid`) with metadata about the database itself and about structure and properties of user data. When a user creates a new table, the coordinator stores information about its schema, ownership, and distribution type while the actual content of the table is stored on the segment.

Standby coordinator

The **standby coordinator** serves as a warm standby: it is kept up to date and ready to take over, but it is not processing queries unless activated. The standby coordinator is optional but highly recommended.

If the primary coordinator fails, there is no automatic switching to the standby coordinator. Instead, ADB relies on administrator intervention. For this, you can use the Activate Standby cluster action in the web interface of Arenadata Cluster Manager (ADCM).

Data integrity and recovery is implemented using **write-ahead logging (WAL)** inherited from PostgreSQL. WAL ensures that all changes to data files are first recorded in the WAL log and flushed to permanent storage before the actual data pages are modified on disk. This guarantees that even if a crash occurs, the database can be recovered by replaying the WAL records.

Segments

Each **segment** is an independent PostgreSQL database that stores and processes its set of data. ADB distributes user data across segments based on the distribution key that you select when you create a table. Balanced distribution of data and workloads across segments is the key to obtaining the best performance from ADB.

> **TIP**
>
> It is advised that all segment hosts have identical hardware resources and configurations. This is because the coordinator aggregates results only after all segments complete their work, so the ADB performance will be as high as the slowest segment server in the cluster. If one segment is significantly slower than the others, it will delay the entire query.

Primary segments

Primary segments are active nodes that store data, receive query plans, and execute queries. They run local database operations on their sets of data and send the results back to the coordinator.

Mirror segments

Mirror segments provide high availability support for primary segments. If a primary segment becomes unavailable, the system automatically fails over to the mirror copy. The mirror then starts acting as a primary segment, and the unavailable primary segment becomes a mirror segment. The administrator must recover the failed segment, and then exchange the primary and mirror segments so they are in their initial (**preferred**) roles.

A mirror segment must always reside on a different host than its primary segment. Two mirror configurations exist:

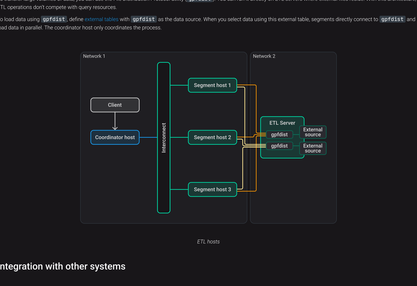
- Group mirroring
- Spread mirroring

Group mirroring

With **group mirroring**, all mirror segments for primary segments of a host are put on one backup host. For example, in the image below, the `Primary 0` and `Primary 1` segments reside on `Segment host 1`, and their mirrors `Mirror 0` and `Mirror 1` reside on `Segment host 2`.

Key characteristics of group mirroring:

- It is the least expensive option because it can be achieved with two hosts only.
- It leads to unbalanced load in case of failure. When a host fails, its mirror host will get double the workload: in addition to its own primary segments (`Primary 2` and `Primary 5` on the image below), its mirrors (`Mirror 0` and `Mirror 1`) will act as primary segments. The host performance will degrade by 50% or more.



group mirroring

Spread mirroring

With **spread mirroring**, mirrors for each host's primary segments are spread across as many hosts as there are segments per host. For example, in the image below, the `Primary 0` and `Primary 1` segments reside on `Segment host 1`, and their mirrors reside on different hosts: `Mirror 0` on `Segment host 2`, and `Mirror 1` on `Segment host 3`.

Comparing to group mirroring:

- Better fault tolerance. Host failures affect only one mirror per host, minimizing workload disruption. On the image below, if `Segment host 1` fails, `Segment host 2` will have `Mirror 0` activated, and `Segment host 3` will have `Mirror 1` activated. The load on each host will increase by 50%, and this extra load is evenly distributed among hosts.
- More expensive. This configuration requires the cluster to have at least one more host than there are segments per host.

Spread mirroring

Interconnect

The **interconnect** is a high-speed network layer that enables communication between segments during query execution. A 10-Gigabit system, or faster, is recommended.

Most database operations run across all segments in parallel and require data motion (data moving between segments). The interconnect is used for data motion, and slow interconnect can lead to delays in such operations.

The interconnect is not required for queries executed on a single segment (targeted query), particularly those filtered by the distribution key where all necessary data can be found on the segment.

By default, the interconnect uses User Datagram Protocol with flow control (UDPIFC). You can select the interconnect type (`udpifc`, `tcp`, or `proxy`) in the ADB configuration parameters.

Use ADB for ETL

Production systems may deploy designated servers for the extract, transform, and load (ETL) purposes outside the ADB cluster. These external servers can connect to the ADB cluster via standard protocols like ODBC, JDBC, or libpq.

To transfer large volumes of data, you can use the File Distribution Protocol utility (`gpfdist`). You can run it directly on ETL servers where external files reside. With this architecture, ETL operations don't compete with query resources.

To load data using `gpfdist`, define external tables with `gpfdist` as the data source. When you select data using this external table, segments directly connect to `gpfdist` and load data in parallel. The coordinator host only coordinates the process.

ETL hosts

Integration with other systems

For integration with diverse data sources and various data formats, ADB uses Platform Extension Framework (PXF) and specialized connectors.

PXF is a data access framework that allows you to query external systems directly. It enables federated queries: you can access and combine data from different sources with a single query. It also supports filter pushdown, which lets external data sources filter data for the `WHERE` clause on their side and thus reduces the amount of data that is transferred to ADB. PXF allows you to handle multiple data formats including Avro, OCF, CSV, Text, ORC, and JSON.

On top of PXF, connectors are built to enable data transfer between the cluster and particular external systems (such as file storage, databases, and streams).

Built-in PXF connectors enable integration with Oracle Database, S3, HBase, Hadoop, HDFS, Hive, and JDBC sources. The Enterprise Edition of ADB provides the following additional connectors: ADB ClickHouse Connector, ADB to Kafka Connector and Kafka to ADB Connector, ADB Spark 3 Connector, and ADB to ADB Connector.

Connectors

Additionally, to extend native SQL capabilities, ADB provides database extensions, such as PostGIS for support of geographic objects or *plpgsql* for support of the PL/pgSQL language. For the full list of extensions available in ADB, refer to Supported extensions.

Advanced cluster management tools

As part of the Enterprise Edition, the following solutions are available in ADB to enhance database management and monitoring:

- Arenadata DB Control (ADB Control), which provides real-time monitoring of SQL commands and transactions, sessions, resource groups, system metrics, and more.
- Arenadata DB Backup Manager (ADBM), which is a fault tolerant system for ADB binary backup management.

Data model

Daria Barysheva

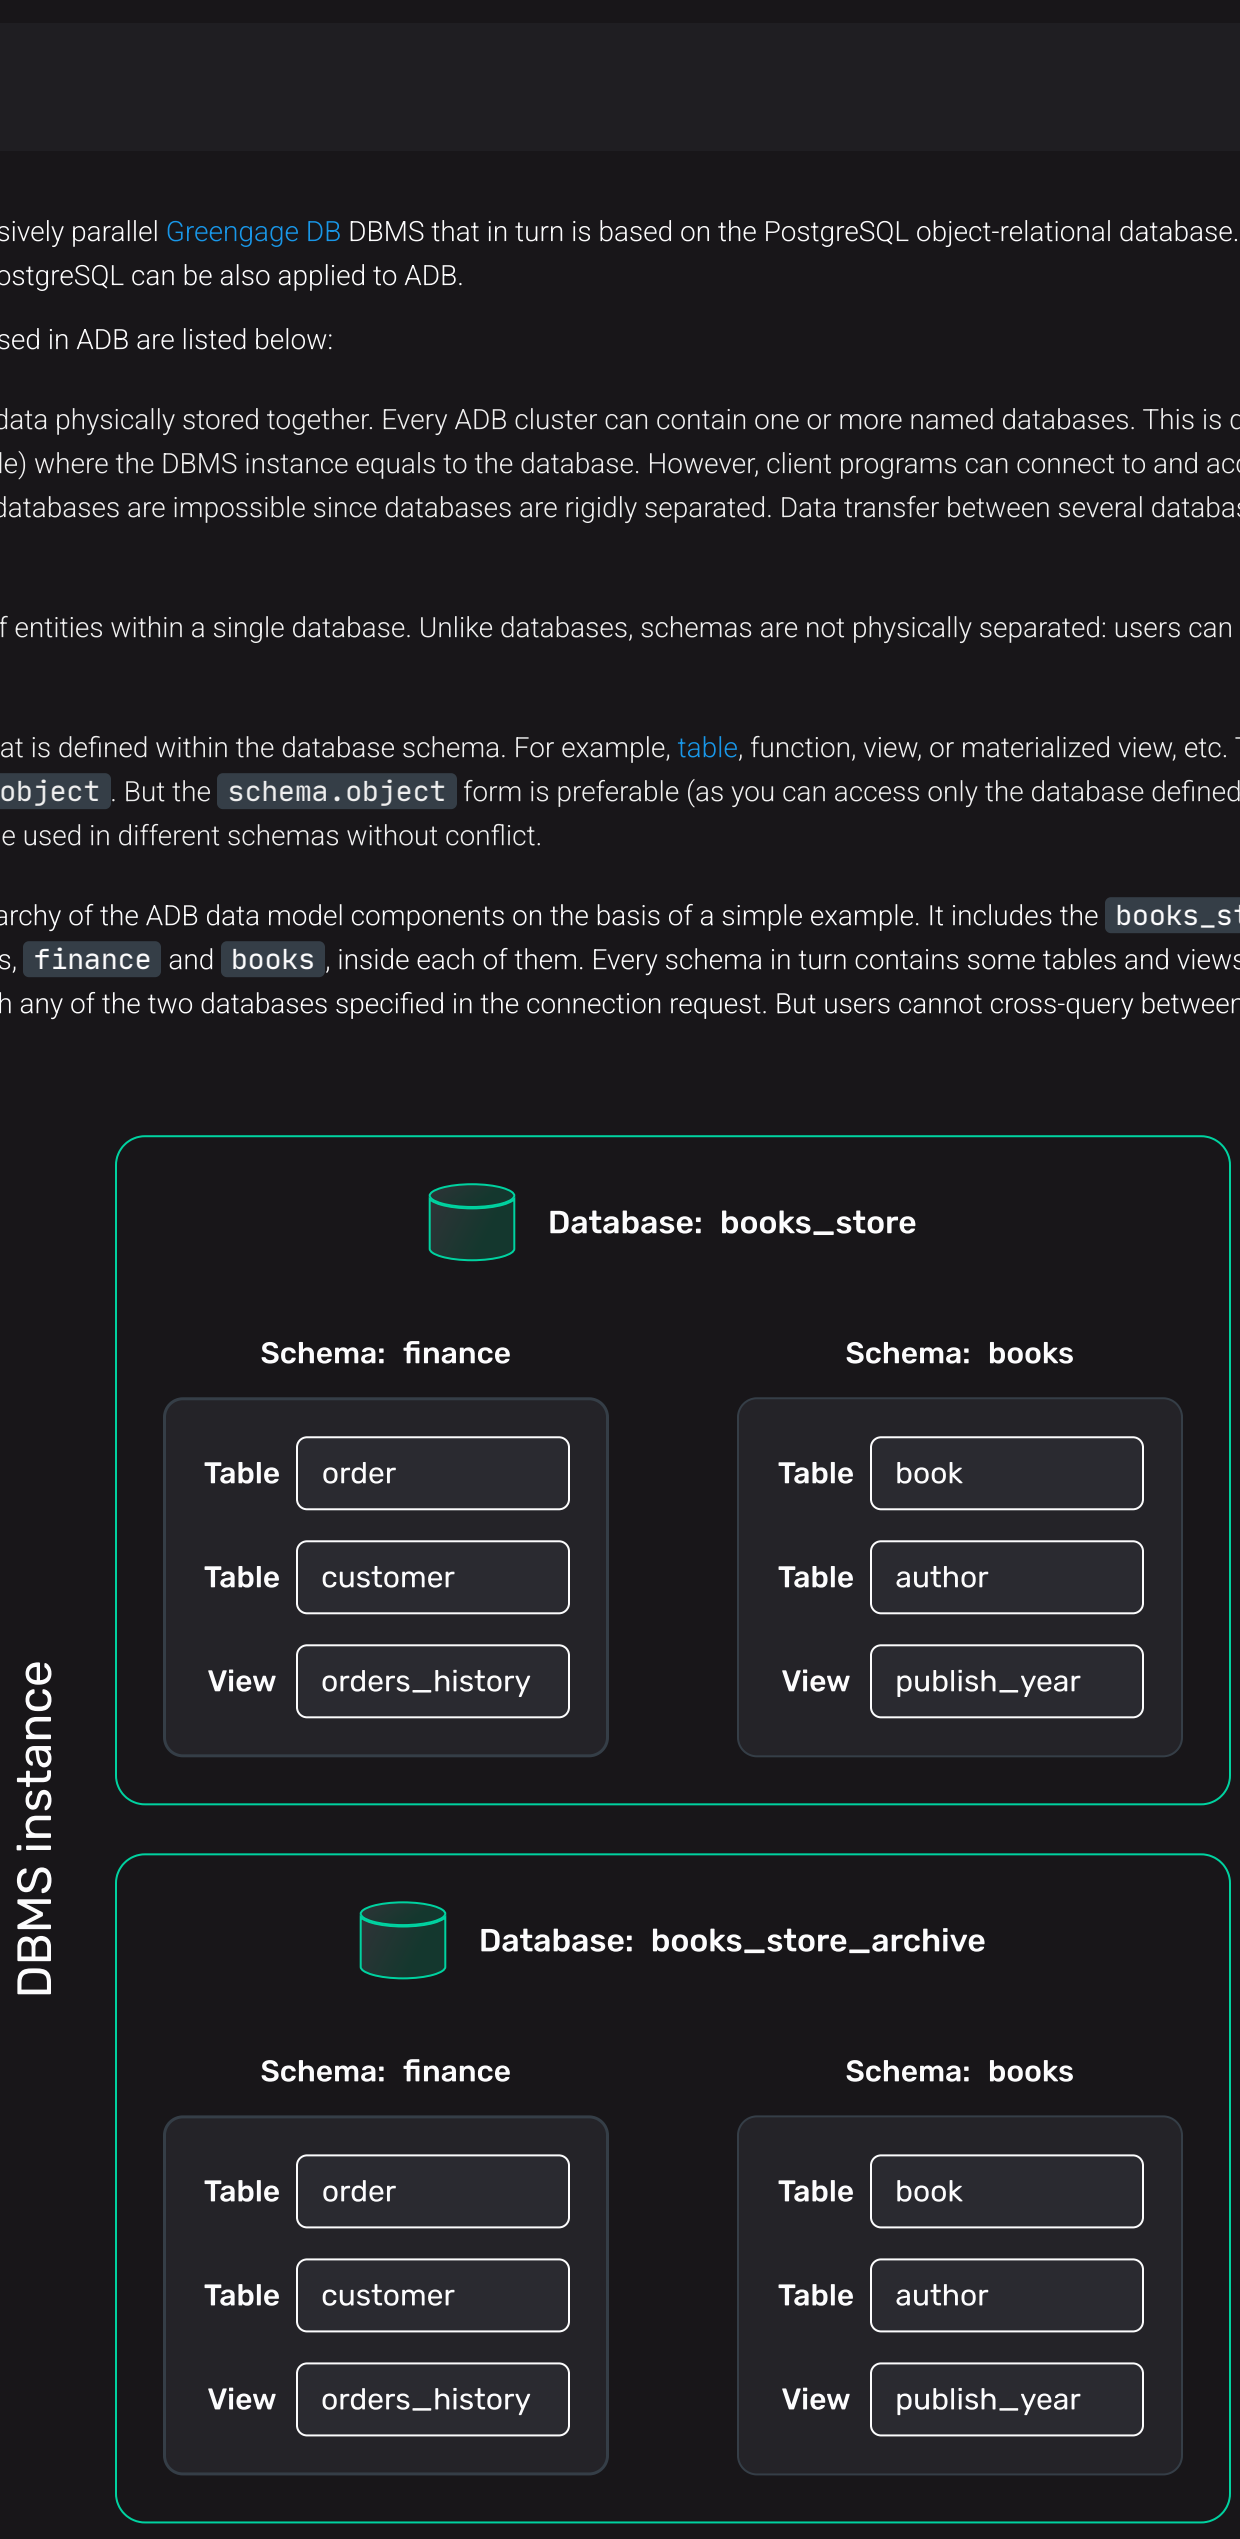
To Table of Contents

ADB is built on the open-source massively parallel Greengage DB DBMS that in turn is based on the PostgreSQL object-relational database. That is why most of the data model concepts that make up the core of PostgreSQL can be also applied to ADB.

The main data model components used in ADB are listed below:

- Database. This is a collection of data physically stored together. Every ADB cluster can contain one or more named databases. This is different from some other database management systems (e.g. Oracle) where the DBMS instance equals to the database. However, client programs can connect to and access only one ADB database at a time — cross-queries between different databases are impossible since databases are rigidly separated. Data transfer between several databases is also impossible by the DBMS functionality.
- Schema. This is a logical union of entities within a single database. Unlike databases, schemas are not physically separated: users can access multiple schemas at a time (if they have the necessary privileges).
- **Object**. This is any other entity that is defined within the database schema. For example, table, function, view, or materialized view, etc. To access objects, you can use the ANSI standard: `database.schema.object`. But the `schema.object` form is preferable (as you can access only the database defined in the current connection anyway). Notice that the same object name can be used in different schemas without conflict.

The picture below illustrates the hierarchy of the ADB data model components on the basis of a simple example. It includes the `books_store` and `books_store_archive` databases with two custom schemas, `finance` and `books`, inside each of them. Every schema in turn contains some tables and views. In this case, users can access both schemas at a time while working with any of the two databases specified in the connection request. But users cannot cross-query between databases.



Data model example

Hardware requirements

Daria Barysheva

Contents

To Table of Contents

ADB

ADB Control

ADBM

Arenadata Enterprise Tools

IMPORTANT

The following system requirements are **minimal**. The target sizing should be calculated based on the customer requirements.

ADB

Coordinator host

- Physical server.
- **CPU:** 8 cores or more.
- **RAM:** 16 GB or more.
- **Disk storage:** separate physical unformatted RAID 10 array (5 GB or more).

Segment hosts

- Physical server.
- **CPU:** 16 cores or more.
- **RAM:** 32 GB or more.
- **Disk storage:** one or more physical unformatted RAID 10 arrays (10 GB or more per array).

ADB Control

NOTE

For more information on the ADB Control architecture, see Arenadata DB Control overview.

ADB Control host

The following are resources that are required on the host where ADB Control is installed.

Service	CPU cores	RAM	Disk storage	Note
Backend Server	6	16 GB	—	Requires additional monitoring of inner metrics queues
Scheduler	2	4 GB	—	Resource consumption may depend on the job configuration (like time periods, batch sizes, scheduling of heavy jobs to run at the same time)
Metrics DB (ClickHouse)	4	16 GB	100 GB	It is better to have the RAM amount that is equal to the compressed data in ClickHouse
Query DB (PostgreSQL)	4	8 GB	200 GB	Storage should be managed carefully so that it won't be exhausted between data cleanup events in ADB Control
Other components: Web UI & UI Backend Server, Service Registry	4	20 GB	10 GB	—
Total	20	64 GB	310 GB	—

ADB hosts

The following are resources that are required on each host of the ADB cluster where an ADB Control agent is installed:

- **CPU:** 4 cores or more.
- **RAM:** 4 GB or more.

ADBM

NOTE

For more information on the ADBM architecture, see Arenadata DB Backup Manager overview.

ADBM host

Arenadata DB Backup Manager can be installed on the same host as ADB Control or on a separate host. ADBM host requires the following minimal resources (for etcd, Backup Manager, Service Registry):

- **CPU:** 4 cores or more.
- **RAM:** 12 GB or more.
- **Disk storage:** 10 GB or more.

ADB hosts

On segment hosts, 30% CPU and 2 GB RAM are utilized by ADBM agent and pgbackrest instance for a one-threaded backup process.

ADBM agents on segment hosts require not less than 1 Gbps network to work. However, the recommended network performance is 10—25 Gbps and higher (the value depends on backup requirements).

Arenadata Enterprise Tools

If you use ET along with your product, take into account the following requirements:

- Virtual server.
- CPU: 4 cores or more.
- RAM: 8 GB or more.
- Disk: 50 GB or more.

Network requirements

Daria Barysheva

Contents

To Table of Contents

Overview

Ports

- ADB ports
- ADB Control ports
- ADBM ports
- Arenadata Enterprise Tools ports

Overview

The network requirements for Arenadata DB installation are listed below:

- One or more dedicated and separate peer-to-peer interconnect networks are required for internal cluster communication.
- All cluster hosts should be connected to interconnect networks.
- All cluster hosts should have IP addresses and the ability to communicate with each other at required speeds.
- `ping` access to any cluster host (ICMP) should be provided.
- The jumbo frame `MTU = 9000` should be specified in interconnect networks to allow packets formed by ADB (`gp_max_packet_size` + overhead) to fit into these frames.
- The Ethernet speed 1 Gbps or more should be provided (the standard value is 10 Gbps).
- There should be no firewall or other software that blocks or slows down the traffic (`firewalld`, `iptables`, `ufw`, etc.). If firewall software is not deactivated, you should configure your software to allow required communication between ADB hosts. For more information, see Greenplum documentation.
- From the outside, the ADB cluster should be available on the following ports:
  - `22` – SSH;
  - `5432` – incoming PostgreSQL interface.
- To access NTP (Network Time Protocol) servers, the coordinator host should be allowed to connect to it (by default, via the `123/udp` port).
- To send cluster component statuses to Arenadata Cluster Manager (ADCM), ADB hosts should be allowed to connect to it (by default, via the `8008/tcp` port). See the Install ADCM article for details on how to install ADCM.
- For offline installation of ADB, access to Arenadata Enterprise Tools repositories deployed on a dedicated host is required (by default, via the `81/tcp` and `443/tcp` ports). The Install Enterprise Tools cluster section contains instructions on how to install Arenadata Enterprise Tools.
- All ports that are listed below should be open on the respective hosts. If you use firewall, add ports to the exception list.

Ports

ADB ports

Coordinator/standby

Service	Port	Protocol	Note
ADB	5432	TCP	SQL client connection port on the ADB coordinator host. Supports clients using the PostgreSQL libpq API. Configurable
Standby coordinator replicator	1025-65535	TCP	Ports used to replicate the coordinator log to the standby coordinator

All cluster hosts

Service	Port	Protocol	Note
Secure shell (SSH): `gpssh`, `gpssh-exkeys`, `gppkg`	22	SSH	Many Greenplum utilities use Secure Copy Protocol (SCP) and Secure Shell (SSH) to manage a cluster and transfer files between hosts
Interconnect	10000-65535	UDP	The interconnect transports database tuples between ADB segments during query execution (for exact ports refer to the `gp_segment_configuration` system table)
Gpperfmon agents	8888	TCP	Connection port for `gpperfmon` agents (`gpmmon` and `gpsmon`) executing on ADB hosts. Configure by setting the `gpperfmon_port` parameter in *postgresql.conf* on coordinator and segment hosts
PXF	5888	TCP	The PXF Java service runs on the `5888` port on each ADB segment host
gpbackup	25 587	TCP	—

Cluster or external hosts

Service	Port	Protocol	Note
gpfdist	8080	HTTP	The `gpfdist` file serving utility can run on ADB hosts or external hosts. You can specify the port range with the `-p` (start port) and `-P` (end port) options when starting the server. The `8080` value is used as the start port by default
gpload	8000-9000	HTTPS	The `gpload` utility runs one or more instances of `gpfdist` with ports or port ranges specified in the configuration file. The `8000-9000` range is used by default and can be changed

ADQM/ClickHouse host

Service	Port	Protocol	Note
ADB ClickHouse Connector	8123	HTTP	All ADB nodes should have access to the `8123` HTTP port on all ADQM/ClickHouse nodes through which you plan to load data

If you use ADB to ADB Connector, ensure that TCP ports that are used in connection are allowed on remote ADB cluster hosts (coordinator host, segment hosts, standby host). You can obtain the list of these ports using the following query on the remote ADB cluster:

```
SELECT port FROM gp_segment_configuration;
```

Add exceptions for the ports from the command output in case of using firewall.

ADB Control ports

NOTE

For more information on the ADB Control architecture, see Arenadata DB Control overview.

ADB Control host

Service	Port	Protocol	Note
Service Registry	6567	gRPC (HTTP 2.0)	gRPC endpoint of Service Registry instances
	8761	HTTP	—
UI Backend Server	6566	gRPC (HTTP 2.0)	—
	8890	HTTP	—
	81	HTTP	Entry to the ADB Control UI
Backend Server	6565	gRPC (HTTP 2.0)	—
	8081	HTTP	—
Scheduler	6572	gRPC (HTTP 2.0)	—
Query DB (PostgreSQL)	5433	TCP	The outside port is mapped to `5432` inside a container
Metrics DB (ClickHouse)	8123	HTTP	HTTP API port for HTTP requests. Used by JDBC, ODBC, and web interfaces
	9000	TCP	Native protocol port (also referred to as ClickHouse TCP protocol). Used by ClickHouse applications and processes like `clickhouse-server`, `clickhouse-client`, and native ClickHouse tools. Used for distributed queries via inter-server communication
Migration	8899	HTTP	—

ADB hosts

Service	Port	Protocol	Note
Agent	6581	TCP	Port for the utility service that is used to manage GUCs which are changed via ADB Control
Agent	5701	TCP	Port that is used as a part of the Hazelcast (distributed cache) cluster node address. The port should be opened on every ADB cluster host (with the ADB Control agent) since it is used for communication between Hazelcast cluster nodes
Agent	From `36801` to `36801 + <number of ADB hosts> - 1`	TCP	Range of allowed outbound ports for connections to other members or clients within a Hazelcast cluster. The ports should be opened on every ADB cluster host with the ADB Control agent

ADBM ports

NOTE

For more information on the ADBM architecture, see Arenadata DB Backup Manager overview.

ADBM host

Service	Port	Protocol	Note
Backup Manager	6570	TCP	—
	8870	TCP	—
	8988	TCP	The outside port is mapped to `8843` inside a container
Service Registry	6567	TCP	—
	8761	TCP	—
PostgreSQL	5432	TCP	The PostgreSQL database service is available on *localhost* and the default PostgreSQL port is `5432`
etcd	2391 2392 2393	TCP	The outside ports are mapped to `2379` inside each instance of etcd correspondingly

ADB hosts

Service	Port	Protocol	Note
Agent	6571	TCP	The port through which gRPC calls from ADBM to agents come

Arenadata Enterprise Tools ports

Port	Protocol	Note
443	TCP	Port that is used by Docker Registry
81	TCP	Port that is used to access repositories during offline installation

Software requirements

Overview

Requirements for Astra Linux and Ubuntu

Operating system prerequisites

Overview

The software requirements for Arenadata DB installation are listed below:

1. ADB supports the following operating systems:
   - Ubuntu 22.04. See Requirements for Astra Linux and Ubuntu below.
   - AltLinux 10.2 SP (for the Enterprise edition of ADB).
   - RED OS 7.3 Certified edition (for the Enterprise edition of ADB).
   - Astra Linux 1.7.6 "Orel" SE and Astra Linux 1.7.6 "Voronezh" (for the Enterprise edition of ADB). See Requirements for Astra Linux and Ubuntu below.
2. If you use ClickHouse or PostgreSQL as external storage systems for ADB Control/ADBM (see Metrics DB and Query DB in Arenadata DB Control overview), the required versions of these databases are:
   - ClickHouse 22.8 – 25.9
   - PostgreSQL 12.20
3. ADB uses Docker as a containerization platform for some services (for example, ADB Control and ADBM) and Enterprise Tools. ADB supports Linux vendor-specific Docker engines. You can also use pre-installed Docker by setting the ***Use existing docker*** flag when configuring the ADB cluster.

IMPORTANT

Starting with ADB 6.27.1 RH, ADB Control rewrites Docker settings in the */etc/docker/daemon.json* file for security purposes. Thus, if you need to modify this file, set the ***Use existing docker*** option when configuring ADB. This option will also allow you to use Docker in the rootless mode.

4. ADB needs Java 17 for some services (e.g. PXF, ADB Control, and ADBM). In all operating systems except Astra Linux, no additional Java installation is needed since Java comes with the main operating system repository. In Astra Linux, before ADB installation, you should install Java manually and fill in the Java path in the ***JAVA_HOME*** field when configuring the ADB cluster. This step is also necessary in other operating systems if you use Java 17 with a path different from the default one.
   The default Java paths for supported operating systems are listed below.

Ubuntu

/usr/lib/jvm/java-17-openjdk-amd64

RED OS

/usr/lib/jvm/jre-17-openjdk

AltLinux

/usr/lib/jvm/jre-17

IMPORTANT

- If you plan to use custom Java (such as Axiom), Java 17 is required for installation.
- For Astra Linux, the ***JAVA_HOME*** field is mandatory starting with ADB 6.27.1 58.

5. The minimal ADCM version is 2.6.0.
6. If you use ADBM, its minimal version for ADB 7 is 2.8.0.
7. If you use ADB Control, its minimal version for ADB 7 is 4.15.0.
8. ADB requires the `en_US.UTF-8` operating system locale on all cluster hosts. Yet you do not need to select this locale as default. This locale is present by default in all supported operating systems except Astra Linux. In the case of Astra Linux, the locale is automatically added during ADB installation. To view available locales, run the following command:

```
$ localectl list-locales
```

9. It is recommended to switch off any antivirus software before ADB installation and during the ADB operation process. In case of using antivirus, please contact your antivirus software vendor to find out the settings necessary to allow ADB.
10. Only Latin characters and digits are allowed for ADB database objects. These characters are treated as reserved: `"` , `&` , `'` , `` ` `` , (space), `{` , `}` , `;` , `<` , `>` , `\` , `~` , `|` . If such characters are present, Arenadata DB Backup Manager will not be able to back up/restore a database.
11. During ADB installation, a bundle assigns the necessary permissions to the specific files and directories it creates, regardless of the `umask` value on cluster hosts.
12. During ADB installation, the following changes are made at the operating system level. Do not change any of the objects listed below.
    - The following system files are modified:
      - */etc/hosts* (optionally)
      - */etc/hostname* (optionally)
      - */etc/chrony.conf* (if you install Chrony)
      - */etc/ssh/sshd_config* (always)
      - */etc/security/limits.conf* (always)
    - A service file for configuring cgroup v2 for ADB is created at */etc/systemd/system/cgroup_v2_gpdb.service*;
    - New files are created in the */sys/fs/cgroup* directory.
13. The installation process creates a new file in the */var/spool/cron/* folder for the ADB system user (by default, `gpadmin`). All technical accounts should be able to change that file as well (via `crontab -e -u gpadmin`). ADB adds cron jobs to run the cluster maintenance scripts – their schedule and arguments should be modified using the corresponding section in the ADB configuration parameters.
14. For online installation of ADB, all cluster hosts should have access to Arenadata repositories specified on the Configuration tab in the ADB cluster menu available via ADCM UI (see ***Arenadata repo url*** and ***Monitoring repo url*** fields). For offline installation, provide access to the host where the Enterprise Tools cluster is installed.
15. For both online and offline installation, all cluster hosts should have access to the repositories that are listed below (or local mirrors should be created):
    - AltLinux: ftp.altlinux.org
    - Astra Linux: download.astralinux.ru
    - RED OS: repo.red-soft.ru and repo1.red-soft.ru
    - Ubuntu: archive.ubuntu.com/ubuntu

Requirements for Astra Linux and Ubuntu

1. ADB, like other analytical DBMS, is optimized to work with generic kernels. Using the low/latency kernels may not provide optimal performance for tasks that are typical for analytical data processing. Due to this, for proper operation of ADB, it is recommended to use generic cores only.
2. You should also consider version compatibility.

NOTE

ADB 6 was built upon cgroup v1. Starting with version 7, ADB uses cgroup v2 that is the default in all supported operating systems.

Operating system prerequisites

Below is the list of prerequisites for your operating system environment to ensure proper ADB operation. You can either prepare the environment manually on all ADB hosts, or select the corresponding configuration parameters in the ADB service to automatically apply the recommended settings during ADB installation.

Before installing ADB, run the Precheck cluster action, which includes verification of the host operating system parameters.

Requirement	Name of ADB configuration parameter

The */etc/hosts* file contains hostnames of all cluster hosts: coordinator host, standby coordinator host, and segment hosts. For example:
`192.168.1.10 mdw.example.com`
`192.168.1.20 smdw.example.com`
`192.168.1.30 sdw1.example.com`
`192.168.1.40 sdw2.example.com`
Alternatively, DNS can be used for hostname resolution
	Edit /etc/hosts

Security Enhanced Linux (SELinux) is disabled	***Disable linux security module*** (requires host reboot)
IPv6 is disabled	***Disable IPv6***
The value of the `MaxStartups` parameter of the OpenSSH Daemon (sshd) is `1000:30:1022`	***Set up MaxStartups for sshd***
Transparent Huge Pages in the Linux kernel are disabled	***Set up GRUB for DBMS*** (requires host reboot)
The following limits are set for the default database user in the */etc/security/limits.conf* file: - The soft and hard limits for the number of open file descriptors are set to `524288`. - The soft and hard limits for the number of processes are set to `150000`.	***Set up ulimits for DBMS user***
The firewall is disabled on ADB hosts	***Disable firewall***

The recommended kernel parameters are as follows (use the `sysctl -a` command to view all kernel settings):
`kernel.core_pipe_limit = 0`
`kernel.core_uses_pid = 1`
`kernel.msgmax = 65536`
`kernel.msgmnb = 65536`
`kernel.msgmni = 2048`
`kernel.sem = 250 2048000 200 8192`
`kernel.shmmni = 4096`
`kernel.sysrq = 1`
`net.core.netdev_max_backlog = 10000`
`net.core.rmem_max = 2097152`
`net.core.wmem_max = 2097152`
`net.ipv4.conf.all.arp_filter = 1`
`net.ipv4.conf.default.accept_source_route = 0`
`net.ipv4.ip_local_port_range = 12000 65535`
`net.ipv4.ipfrag_high_thresh = 41943040`
`net.ipv4.ipfrag_low_thresh = 31457280`
`net.ipv4.ipfrag_time = 60`
`net.ipv4.tcp_max_syn_backlog = 4096`
`net.ipv4.tcp_syncookies = 1`
`vm.dirty_background_bytes = 1610612736`
`vm.dirty_background_ratio = 0`
`vm.dirty_bytes = 4294967296`
`vm.dirty_expire_centisecs = 500`
`vm.dirty_ratio = 0`
`vm.dirty_writeback_centisecs = 100`
`vm.overcommit_memory = 2`
`vm.overcommit_ratio = 95`
`vm.swappiness = 10`
`vm.zone_reclaim_mode = 0`
	Sysctl parameters

IMPORTANT

If you change the ***Disable linux security module*** and ***Set up GRUB for DBMS*** parameters, reboot the affected hosts. To do so:

- To apply settings on the cluster hosts during installation – set the ***Reboot cluster servers after installation*** flag in the ***Install*** or ***Reinstall*** cluster action.
- To apply settings on hosts that you add to the ADB service:
  - Set the ***Reboot new segment host after installation*** flag in the ***Move Host Segment*** cluster action.
  - Set the ***Reboot new servers after installation*** flag in the ***Expand*** or ***Init Standby Master*** cluster action.

Otherwise, these settings will not apply to the hosts. If the ***Reboot cluster servers after installation*** flag was not set, it is recommended to stop the cluster and reboot the hosts manually to apply the specified settings.

Installation

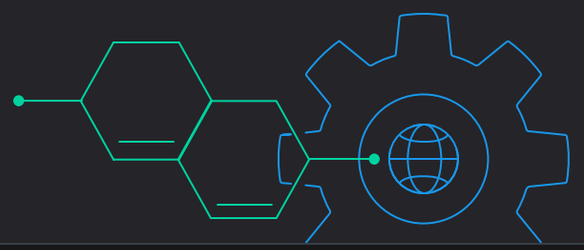
To Table of Contents

This tutorial guides you through the process of installing an Arenadata DB (ADB) cluster. The easiest way to install it is to use Arenadata Cluster Manager (ADCM) — a separate Arenadata product designed for simple, convenient, and fast software deployment and exploitation.

You can install ADB via ADCM in two ways.

Online installation

on hosts with access to Internet



Offline installation

on hosts without access to Internet

Online installation

To Table of Contents

This topic describes **online** installation of ADB. It can be applied to the hosts with access to Internet.

The process of online installation via ADCM includes the following steps.

Step 1.

Install ADCM

Step 2.

Prepare hosts

Step 3.

Install ADB cluster

Install ASCOM

Contents

- Step 1 Check prerequisites

Download the Platform 6 Install Platform 6 Windows Updater Developer Components Simulators Help.exe installer.

Run Install Platform 6 Windows Updater Developer Components Simulators Help

Prepare hosts

To Table of Contents

To manage a cluster and its nodes via ADCM, it is necessary to prepare hosts for a cluster and link these hosts to ADCM. This is the function of ADCM **hostproviders** — special plugins for ADCM, which encapsulate the complex mechanism of interaction between ADCM and the hosts controlled by it.

ADCM supports several types of hostproviders. For more information on how to configure hostproviders and use them to create hosts, refer to the following documentation:

- SSH
- Yandex Cloud
- VCloud (VMware)
- Cloud.ru Advanced
- CROC Cloud
- ADB Cloud Bundle

CAUTION

Starting with the 6.23.3.44 version, ADB supports both FQDN and short host names. For the previous ADB versions, it is not recommended to use FQDNs (as FQDNs cause errors during the ***Expand*** action and a workaround is needed).

Create a cluster

Daria Barysheva

Contents

To Table of Contents

Step 1. Download a cluster bundle

Step 2. Upload a cluster bundle to ADCM

Step 3. Create a cluster based on the uploaded bundle

In ADCM a **cluster** means a set of services running on a set of hosts.

Clusters distributions for ADCM are made in the form of so-called bundles. Generally a bundle is a regular archive that includes a description and software logic of cluster deployment and exploitation.

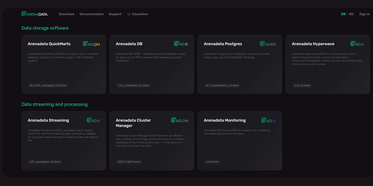
The steps for adding a cluster to ADCM are listed below.

NOTE

If you use the Enterprise Edition, skip the step 1, get a bundle from the Arenadata support team, and move to the step 2.

Step 1. Download a cluster bundle

1. Go to https://network.arenadata.io/ and choose ***Arenadata DB***.



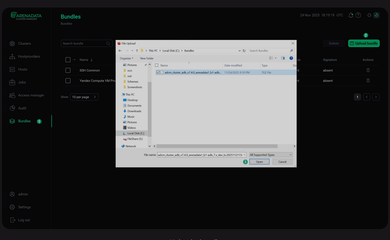
Switch to the bundle download page

2. On the next page, download a bundle for the required version of ADB.

Step 2. Upload a cluster bundle to ADCM

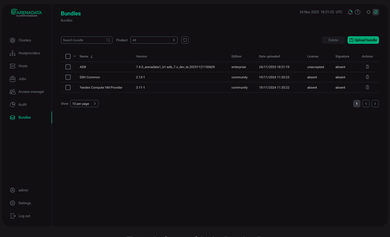
To upload a bundle to ADCM, follow the steps:

1. Select the ***Bundles*** item in the left navigation menu and click ***Upload bundle***.
2. Select a bundle in the Open File Dialog.



Upload a bundle

3. As a result of the performed actions, a bundle is displayed on the ***Bundles*** page.



The result of successful uploading a bundle

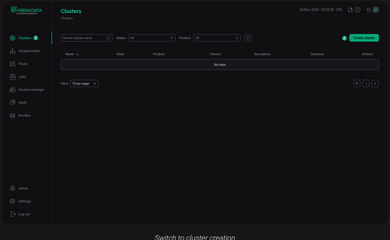
Step 3. Create a cluster based on the uploaded bundle

IMPORTANT

When creating a cluster via the ADCM web interface, you generate a new ADCM cluster instance. It means only adding the cluster to ADCM – at this stage no services are deployed.

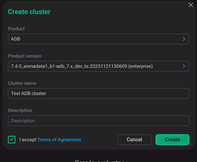
The steps for cluster creation are given below:

1. Select the ***Clusters*** item in the left navigation menu and click ***Create cluster***.



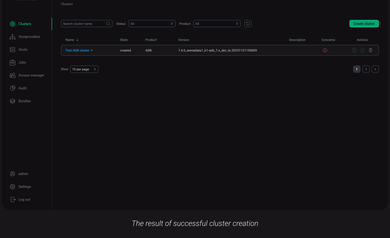
Switch to cluster creation

2. In the opened dialog, describe a new cluster instance:
   - Select an uploaded cluster bundle in the ***Product*** field.
   - Select a bundle version in the ***Product version*** field. Several versions become available in the case of different versions of the same bundle being uploaded.
   - Enter a cluster name in the ***Cluster name*** field.
   - Enter a cluster description in the ***Description*** field if necessary.
   - Set the ***I accept Terms of Agreement*** flag to sign the license agreement. This flag is displayed only for Enterprise bundles. To read the agreement text, refer to the ***Terms of Agreement*** link. You can also sign the license agreement on the ***Bundles*** page by clicking the desired product bundle.
   - Click ***Create***.



Create a cluster

3. As a result, the created cluster instance is displayed on the ***Clusters*** page.



The result of successful cluster creation

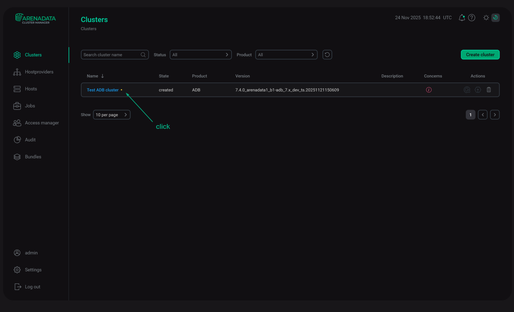
Add services

Daria Barysheva

To Table of Contents

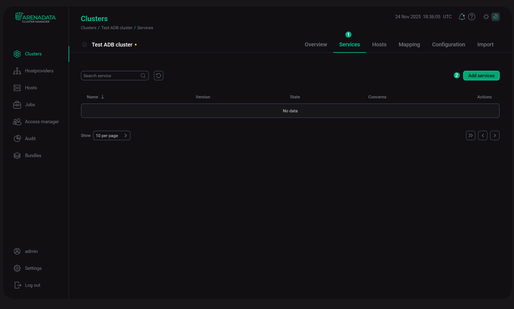
In ADCM a **service** means a software that performs some function. Examples of services for ADB clusters: ADB, ADB Control, Chrony, etc. The steps for adding services to a cluster are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



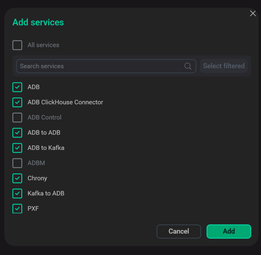
Select a cluster

2. Open the ***Services*** tab on the cluster page and click ***Add service***.



Switch to adding services

3. In the opened dialog, select services that should be added to the cluster and click ***Add***.



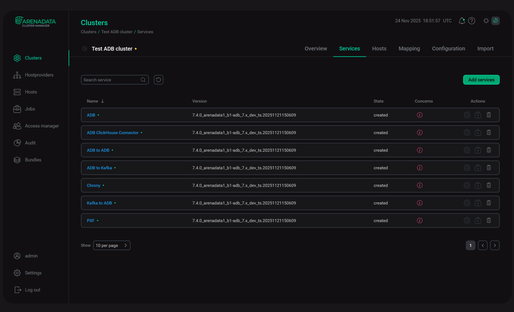
Select services

The brief description of available services is listed below. `CE` means the Common Edition of ADB, `EE` — the Enterprise Edition of ADB.

Services that can be added to the ADB cluster

Service	Mandatory	Edition	Purpose
ADB	Yes	CE/EE	A core service, corresponding to the massively parallel DBMS based on Greengage DB
Chrony	No	CE/EE	A time service. Provides time synchronization for the cluster hosts, that is necessary for the cluster to work correctly. If the time service is already configured on the hosts, there is no need to install Chrony
PXF	No	CE/EE	A service that provides ADB interactions with external data sources
ADB ClickHouse Connector	No	EE	ADB ClickHouse Connector — a service that provides two-way ADB interactions with ClickHouse. Requires PXF
ADB to Kafka	No	EE	ADB to Kafka Connector — a service that provides one-way ADB interactions with Kafka. Requires PXF
Kafka to ADB	No	EE	Kafka to ADB Connector — a service that provides one-way Kafka interactions with ADB
ADB to ADB	No	EE	ADB to ADB Connector — a service that provides two-way interactions between ADB clusters
ADBM	No	EE	Arenadata DB Backup Manager — a service for ADB binary backups management. Can be installed only offline
ADB Control	No	EE	Arenadata DB Control (ADB Control) — a service for monitoring, diagnostics, and management of queries, that run in the ADB cluster. Can be installed only offline

4. As a result, the added services are displayed on the ***Services*** tab.



The result of successful adding services to a cluster

NOTE

You can also add services later. The process of adding new services to already running cluster does not differ from installing a service from scratch.

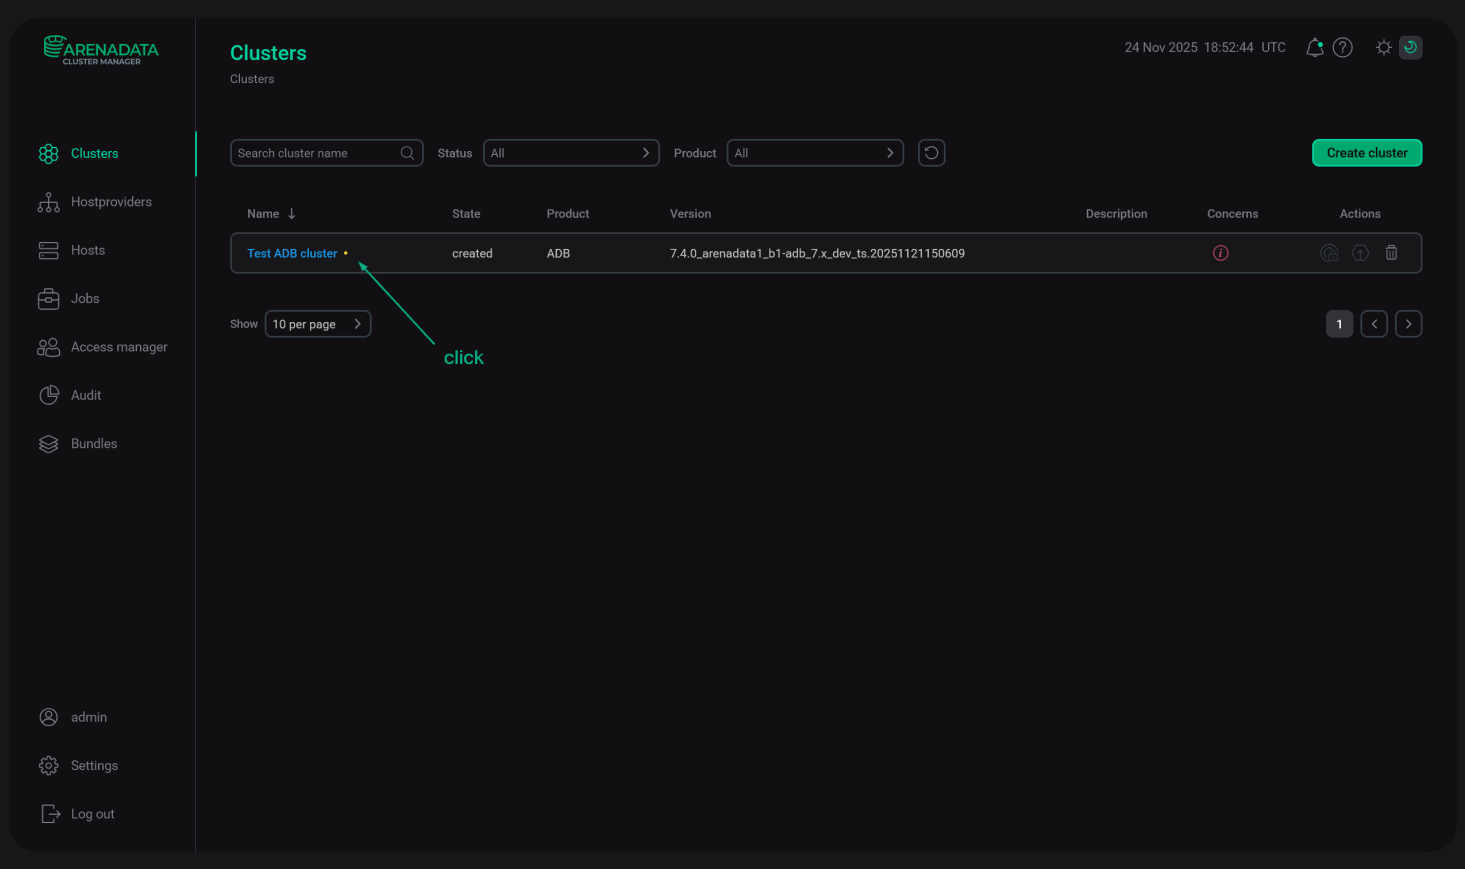
Add hosts to a cluster

Daria Barysheva

To Table of Contents

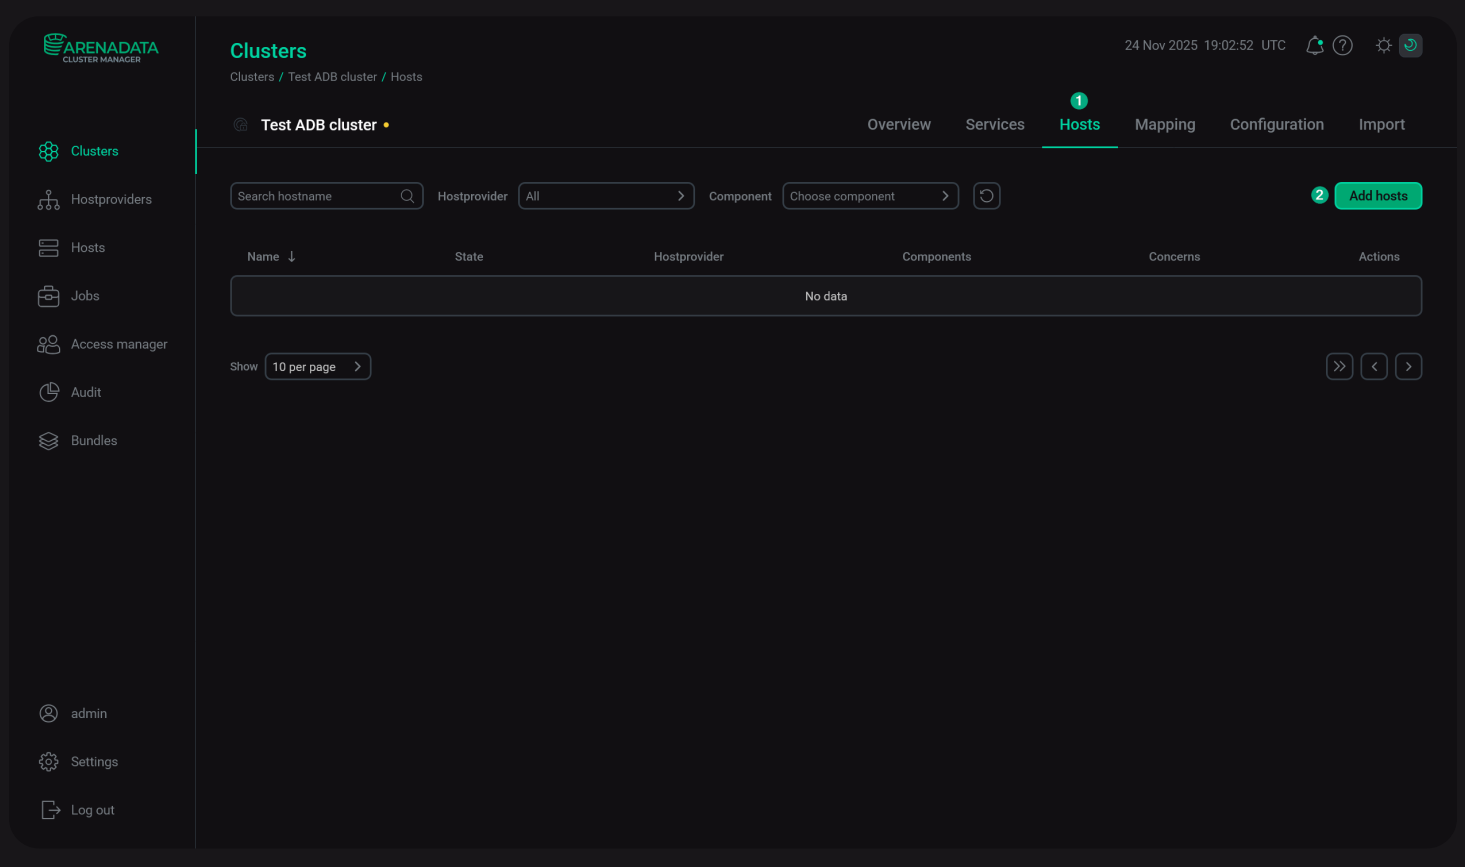
The steps for adding hosts to a cluster are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



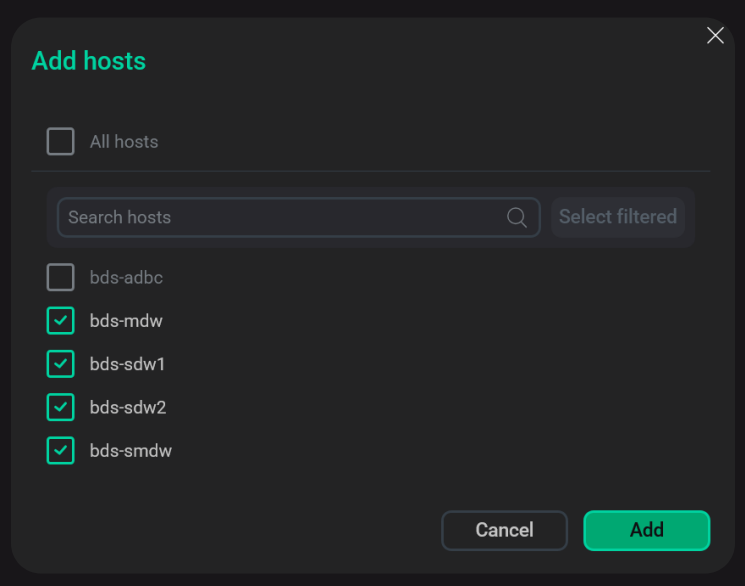
Select a cluster

2. Open the ***Hosts*** tab on the cluster page and click ***Add hosts***.



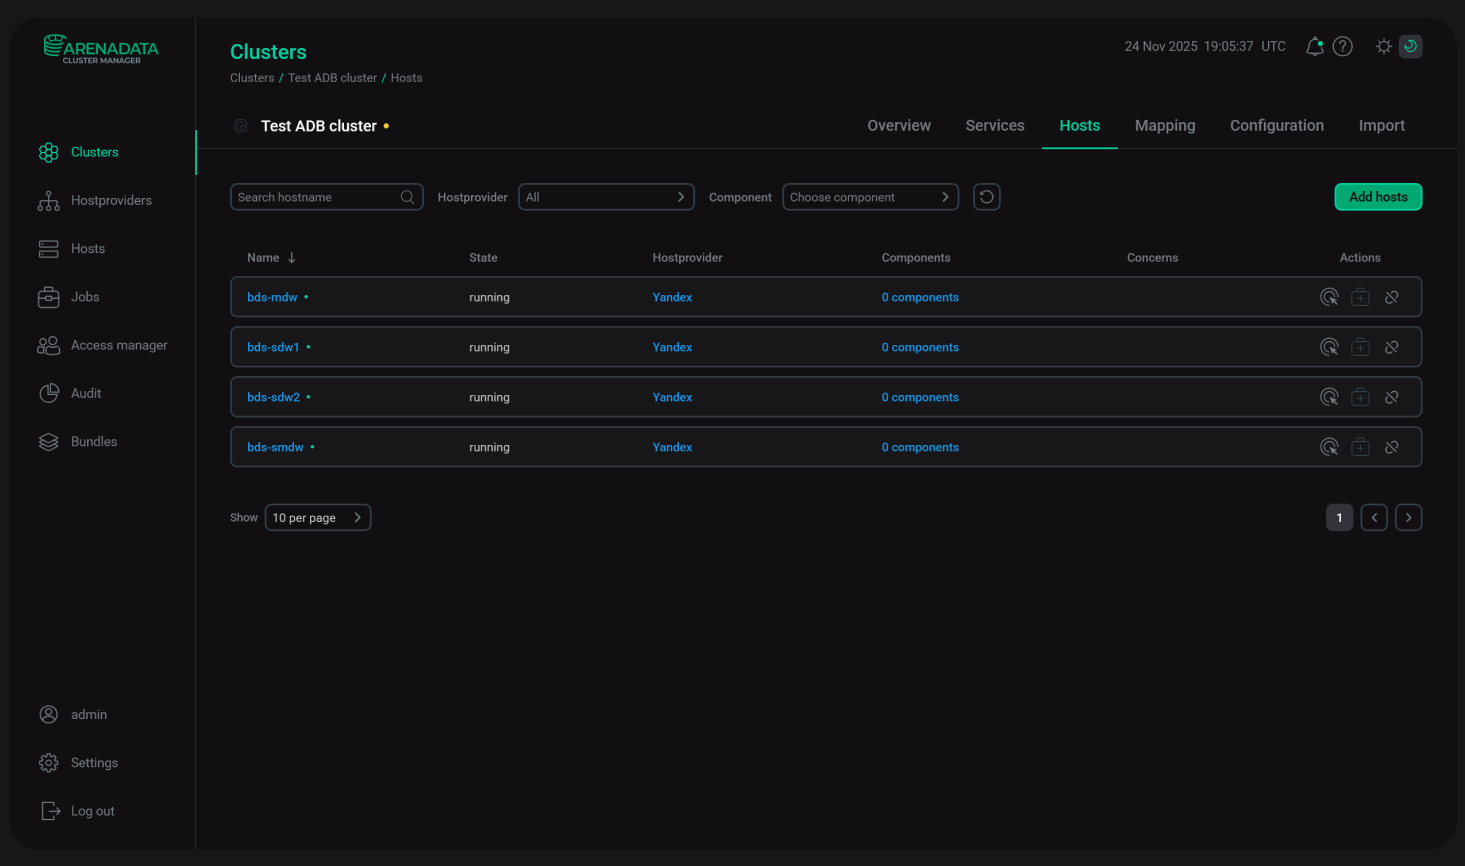
Switch to adding hosts

3. In the opened dialog, select hosts that should be added to the cluster and click ***Add***.



Select hosts

4. As a result, the added hosts are displayed on the ***Hosts*** tab.



The result of successful adding hosts to a cluster

Add components

Daria Barysheva

To Table of Contents

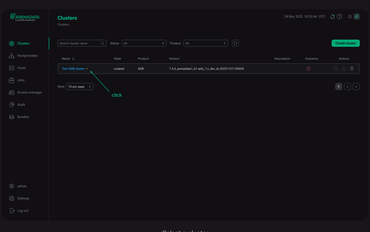
In ADCM a **component** means a part of a service that should be deployed on one or several cluster hosts. For example, ADB service consists of such components as ADB Master, ADB Segment, ADB Standby, etc.

IMPORTANT

Initially, there are no components on any of cluster hosts. You should map components to hosts manually.

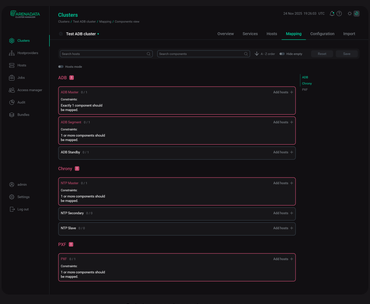
The steps for adding components to hosts are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



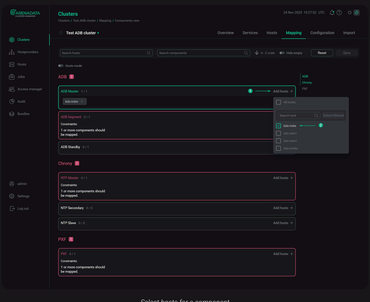
Select a cluster

2. Open the ***Mapping*** tab on the cluster page.



Switch to mapping service components

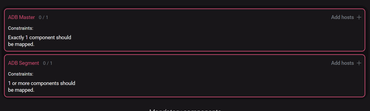
3. In the window that opens, map components to hosts. To assign hosts for each component, click ***Add hosts*** and select hosts in the pop-up window.



Select hosts for a component

Mandatory components

Each service can have mandatory and optional components. Mandatory components are highlighted in red. The ADCM UI also displays how many mandatory components should be installed.



Mandatory components

CAUTION

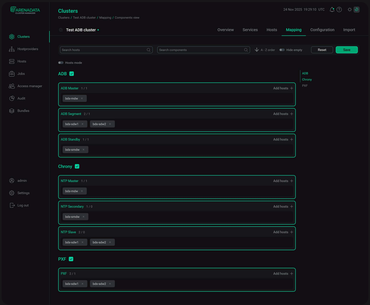
Without assigning a necessary number of hosts to mandatory components, the component mapping cannot be saved.

The typical scheme of mapping components in ADB clusters is described in the table below. It is based on the Enterprise Edition of ADB.

Example of mapping ADB components to hosts

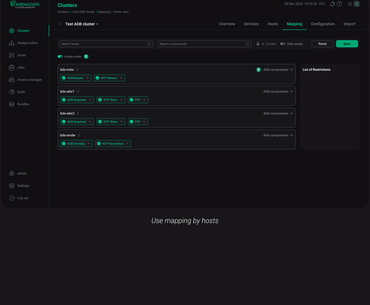
Host	Service	Component	Notes
Coordinator host	ADB	ADB Master	Should be installed on the coordinator host
	Chrony	NTP Master	Should be installed on the coordinator host
Secondary Master Host (Standby)	ADB	ADB Standby	Should be installed on the standby coordinator host
	Chrony	NTP Secondary	Should be installed on the standby coordinator host
Segment host (1..N)	ADB	ADB Segment	Should be installed on each segment host
	Chrony	NTP Slave	Should be installed on each segment host
	PXF	PXF	Should be installed on one or more segment hosts and, optionally, on the coordinator host

4. After component distribution is completed, click ***Save***.



Save mapping of components

Starting with ADCM 2.2.0, you can use another mapping mode — by hosts. To do this, switch on the ***Hosts mode*** toggle and map components to hosts by clicking ***Add components*** for each host sequentially.



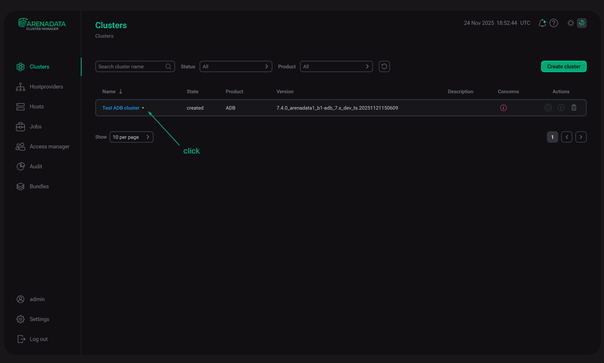
Use mapping by hosts

Configure services

Daria Barysheva

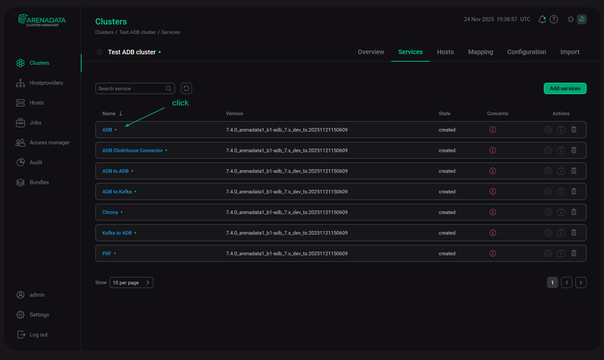
To Table of Contents

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



Select a cluster

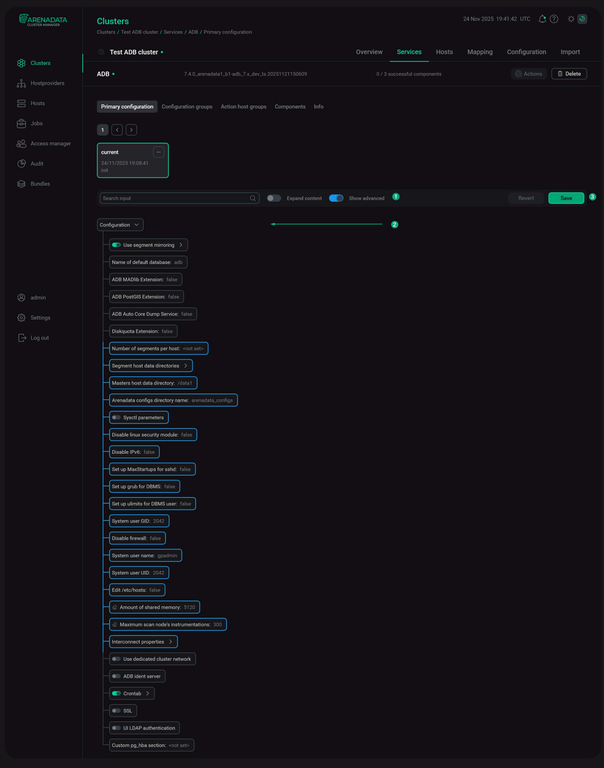
2. Open the ***Services*** tab on the cluster page, find the row that contains the desired service, and click its name in the ***Name*** column.



Switch to configuring a service

3. In the window that opens:

   - Open the ***Primary Configuration*** tab.
   - Switch on the ***Show advanced*** toggle.
   - Fill in configuration parameters of the selected service. The fields highlighted in red are mandatory.
   - Click ***Save***.



Configure a service

Pay attention to the following parameters:

- ***ADB → Edit /etc/hosts***. Set to `true` to let ADB modify the */etc/hosts* file to include hostnames of all cluster hosts. Otherwise, you should modify this file manually or configure a DNS server. Using the ADB service settings, you can also adjust other parameters of the cluster hosts to align them with recommended values.
- ***ADB → Disable linux security module*** and ***ADB → Set up GRUB for DBMS***. Changing these parameters requires host reboot, so it is recommended to set them to `true` before cluster installation and then set ***Reboot cluster servers after installation*** to `true` when launching the Install cluster action to reboot hosts automatically. If you change these parameters after installation, you will have to stop the cluster and reboot hosts manually.
- ***Chrony → NTP servers***. Though this parameter is optional, we recommend to set it to the nearest NTP server, e.g. the one that your company uses.

NOTE

For more information about services configuration parameters, see Configuration parameters.

Configure a cluster

Key concepts

Contents

To Table of Contents

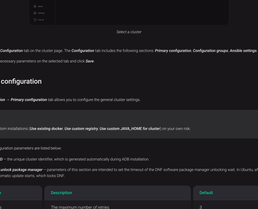
Primary configuration
Configuration groups
Ansible settings

IMPORTANT

There is usually no need to change cluster configuration parameters. You can leave all parameters at the default values.

After creation a new cluster, you can configure it by performing the following steps:

1. Select a cluster on the **Clusters** page. To do this, click a cluster name in the **Name** column.



Select a cluster

2. Open the **Configuration** tab on the cluster page. The **Configuration** tab includes the following sections: *Primary configuration*, *Configuration groups*, *Ansible settings*.
3. Fill in all necessary parameters on the selected tab and click **Save**.

Primary configuration

The *Configuration → Primary configuration* tab allows you to configure the general cluster settings.

CAUTION

Use all custom installations (*Use existing docker*, *Use custom registry*, *Use custom JAVA_HOME for cluster*) on your own risk.

Available configuration parameters are listed below:

- *Cluster UUID* – the unique cluster identifier, which is generated automatically during ADB installation.
- *Timeout to unlock package manager* – parameters in this section are intended to set the timeout of the DNF software package manager unlocking wait. In Ubuntu, after the host reboot, automatic update starts, which locks DNF.

Name	Description	Default
retries	The maximum number of retries	3
delay	The time delay between retries (in seconds)	10

- Paths to the repositories that are used during the installation process depending on the cluster operating system (AltLinux, Astra Linux, RED OS, and Ubuntu). Only the marked repositories are registered on the cluster hosts.

Altlinux 10 repositories

Parameter	Description
Set up Arenadata repo	Whether or not to use the repository that is described in the field *Arenadata repo url*
Arenadata repo url	The repository that is required to install ADB
Set up custom Arenadata enterprise repo	Whether or not to use the repository that is described in the field *Custom Arenadata enterprise repo*
Custom Arenadata enterprise repo	Custom Arenadata Enterprise repository. If not filled in, the default repository will be used
Set up ADB monitoring repo	Whether or not to use the repository that is described in the field *prometheus_repo* (for future use)
prometheus_repo	The repository that is required to install monitoring (for future use)

Astra linux repositories

Parameter	Description
Set up Arenadata repo	Whether or not to use the repository that is described in the field *Arenadata repo url*
Arenadata repo url	The repository that is required to install ADB
Set up custom Arenadata enterprise repo	Whether or not to use the repository that is described in the field *Custom Arenadata enterprise repo*
Custom Arenadata enterprise repo	Custom Arenadata Enterprise repository. If not filled in, the default repository will be used
Set up ADB monitoring repo	Whether or not to use the repository that is described in the field *prometheus_repo* (for future use)
prometheus_repo	The repository that is required to install monitoring (for future use)

redos 7 repositories

Parameter	Description
Set up Arenadata repo	Whether or not to use the repository that is described in the field *Arenadata repo url*
Arenadata repo url	The repository that is required to install ADB
Set up custom Arenadata enterprise repo	Whether or not to use the repository that is described in the field *Custom Arenadata enterprise repo*
Custom Arenadata enterprise repo	Custom Arenadata Enterprise repository. If not filled in, the default repository will be used
Set up ADB monitoring repo	Whether or not to use the repository that is described in the field *prometheus_repo* (for future use)
prometheus_repo	The repository that is required to install monitoring (for future use)

Ubuntu 22.04 repositories

Parameter	Description
Set up Arenadata repo	Whether or not to use the repository that is described in the field *Arenadata repo url*
Arenadata repo url	The repository that is required to install ADB
Set up custom Arenadata enterprise repo	Whether or not to use the repository that is described in the field *Custom Arenadata enterprise repo*
Custom Arenadata enterprise repo	Custom Arenadata Enterprise repository. If not filled in, the default repository will be used
Set up ADB monitoring repo	Whether or not to use the repository that is described in the field *prometheus_repo* (for future use)
prometheus_repo	The repository that is required to install monitoring (for future use)

- *Use existing docker* – a flag that indicates whether to use the existing Docker during the installation of ADB services (e.g. ADB Control, ADBM, Monitoring, Enterprise Tools). If this flag is set, only containers will be deployed, while Docker and Docker Compose installation will be skipped. For more information on Docker requirements, see *Software requirements*.

IMPORTANT

Starting with ADB [7.1.0](), ADB Control rewrites Docker settings in the */etc/docker/daemon.json* file for security purposes. Thus, if you need to modify this file, set the *Use existing docker* option when configuring ADB. This option will also allow you to use Docker in the rootless mode.

- *Use custom registry* – a switcher that determines whether to use a custom registry. When the switcher is activated, the following parameters are available.

Parameter	Description
registry	A custom registry URL in the following form: `<host>:<port>`
prefix	An optional subdirectory name that will be added to the custom registry URL: `<registry>/<prefix>`
Use self-signed certificate	Whether or not to use a self-signed certificate
Self-signed certificate	A self-signed certificate text

Ubuntu

/usr/lib/jvm/java-17-openjdk-amd64

RED OS

/usr/lib/jvm/jre-17-openjdk

ASLinux

/usr/lib/jvm/jre-17

IMPORTANT

- If you plan to use custom Java (such as Azul), Java 17 is required for installation.
- For Astra Linux, the *JAVA_HOME* field is mandatory starting with ADB [6.17.1-36]().

- *Parameter archiving* – a switcher that indicates whether to export ADB settings according to the specified schedule. When the switcher is activated, the *Parameter archiving job* settings field becomes available. Enter a schedule for an export job in that field. The field value should be a valid [cron]() expression. After you edit and save the *Parameter archiving job setting* option, run the cluster action *Reconfigure parameter archiving*.
  Each time a [cron]() job is run, ADB settings are exported to the following directory:

```
/home/gpadmin/arenadata_configs/settings/<timestamp>
```

  where `<timestamp>` is a timestamp of the export job in the `YYYY-MM-DD_HH-mm-ss` format.
  A job execution log is saved to the parameter_archiving.log file.
  Currently, the following settings are offloaded.

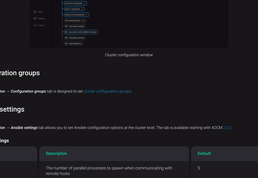
Service	Exported parameters	Relative path
ADB	GUC values for coordinator/segment	/YYYY-MM-DD_HH-mm-ss/_guc_config.json
	Linux Greenplum-related parameters that are exported from etc/sysctl.conf	/YYYY-MM-DD_HH-mm-ss/_sc_config.json
	Resource group parameters	/YYYY-MM-DD_HH-mm-ss/_rg_config.json
ADB Control	Configuration parameters of ADB Control components	/adcs/*
ADBM	Configuration parameters of ADBM components	/adbm/*
PXF	PXF settings that are exported from: - */etc/pxf/conf/pxf-application.properties* - */etc/pxf/conf/pxf-profiles.xml* - *$PXF_BASE/servers/**	/pxf_config/*

- *Vault integration* – a switcher that indicates whether to use HashiCorp Vault to store secrets of ADB services. When the switcher is activated, the following parameters become available.

Name	Description	Default
Address of the Vault server	The Vault server address (e.g. `172.168.1.120` or `vault.domain.com`). Required only if the *Writer authentication method for the Vault server* parameter is set to `token`	–
Port of the Vault server	The Vault server port. Should be specified if the service is published on a port other than HTTPS (443)	443
Internal CA certificate in PEM format (optional)	The internal CA certificate in PEM format that signed the Vault server's certificate	–
Use PEM CA for vault	Defines whether to use the CA certificate in PEM format. If you set this parameter to `true`, you also need to fill in *Internal CA certificate in PEM format (optional)*. Format the multiline plaintext in vault, set *Use PEM CA for vault* to `true`	false
Vault namespace (optional)	The Vault namespace	–
Writer authentication method for the Vault server	The authentication method that is used to connect to the Vault server with write access. Possible values: - `token` - `approle`	approle
Writer Vault token	The application token that is used to connect to the Vault server with write access. Required only if the *Writer authentication method for the Vault server* parameter is set to `token`	–
Writer Vault role ID	The role identifier provided for applications to connect to the Vault server with write access. Required only if the *Writer authentication method for the Vault server* parameter is set to `approle`	–
Writer Vault secret ID	The secret identifier associated with the *Writer Vault role ID* role that is used by applications to connect to the Vault server with write access. Required only if the *Writer authentication method for the Vault server* parameter is set to `approle`	–
Reader authentication method for the Vault server	The authentication method that is used to connect to the Vault server with read access. Possible values: - `token` - `approle`	approle
Reader Vault token	The application token that is used to connect to the Vault server with read access. Required only if the *Reader authentication method for the Vault server* parameter is set to `token`	–
Reader Vault role ID	The role identifier provided for applications to connect to the Vault server with read access. Required only if the *Reader authentication method for the Vault server* parameter is set to `approle`	–
Reader Vault secret ID	The secret identifier associated with the *Reader Vault role ID* role that is used by applications to connect to the Vault server with read access. Required only if the *Reader authentication method for the Vault server* parameter is set to `approle`	–
Mount point for ADB cluster secrets	A mount point that is accessible for read/write operations with the provided ADB cluster authentication parameters. Each service will store secrets on the Vault server at the following path: *<Mount point for ADB cluster>/arenadata/<cluster_name>/service/<service_name>/<component>*	–
Login mount point	A custom authentication mount point. If empty, equals to the authentication method selected in the *Writer authentication method for the Vault server* (write) or *Reader authentication method for the Vault server* (read) field	–

IMPORTANT

- Before editing Vault integration parameters, ensure that Vault is installed and configured.
- Each time you edit and save parameters in the **Vault integration** section, run the cluster action *Reconfigure Vault integration*.
- Currently, Vault can be used to store authentication parameters of ADB Control and ADBM.
- If you need to store credentials for the ADB Control Query DB and Metrics DB in Vault, set up these databases as *external*.



Cluster configuration window

Configuration groups

The *Configuration → Configuration groups* tab is designed to set *cluster configuration groups*.

Ansible settings

The *Configuration → Ansible settings* tab allows you to set Ansible configuration options at the cluster level. The tab is available starting with ADCM [2.0]().

Ansible settings

Name	Description	Default
forks	The number of parallel processes to spawn when communicating with remote hosts	5

Install a cluster

Save for reference

To Table of Contents

Contents

Step 1. Precheck

Step 2. Run installation

- Whole cluster
- Single services

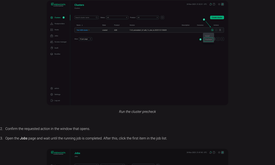
Step 3. Check the cluster state after installation

Step 4. Check the default database

Step 1. Precheck

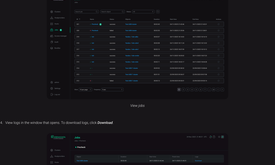
Before installing a new cluster it is recommended to run the **Precheck** action. By doing this, you make sure that all necessary repositories are available, the cluster does not contain hosts with the same IP addresses, and all other prerequisites are met. Do the following:

1. Apply the **Precheck** action to the cluster selected on the **Clusters** page by clicking the ⋮ icon in the **Actions** column.



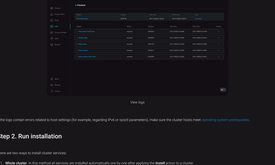
Run the cluster precheck

2. Confirm the requested action in the window that opens.
3. Open the **Jobs** page and wait until the running job is completed. After this, click the first item in the job list.



View jobs

4. View logs in the window that opens. To download logs, click **Download**.



View logs

If the logs contain errors related to host settings (for example, regarding IPv6 or sysctl parameters), make sure the cluster hosts meet operating system prerequisites.

Step 2. Run installation

There are two ways to install cluster services:

1. **Whole cluster** - In this method all services are installed automatically one by one after applying the **Install** action to a cluster.
2. **Single services** - In this method each service is installed manually after applying one or more actions to it. This way is also suitable for installing new services in the already deployed cluster.

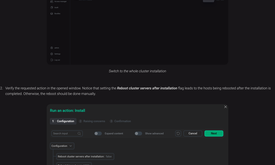
In both cases each service starts automatically after installation.

> **NOTE**
>
> In case of errors, you can find logs of the **Jobs** page.

Whole cluster

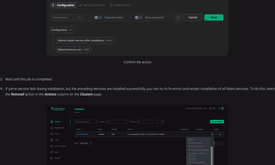
To install all cluster services within a single action, follow the steps:

1. Apply the **Install** action to the cluster selected on the **Clusters** page by clicking the ⋮ icon in the **Actions** column.



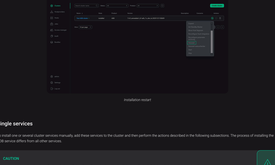
Switch to the whole cluster installation

2. Verify the requested action in the opened window. Notice that setting the **Reboot cluster servers after installation** flag leads to the hosts being rebooted after the installation is completed. Otherwise, the reboot does not occur.



Confirm the action

3. Wait until the job is completed.
4. If some service fails during installation, but the preceding services are installed successfully, you can try to fix errors and restart installation of all failed services. To do this, select the **Reinstall** action in the **Actions** column on the **Clusters** page.



Installation restart

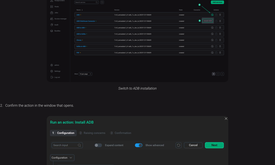
Single services

To install one or several cluster services manually, add these services to the cluster and then perform the actions described in the following subsections. The process of installing the ADB service differs from all other services.

> **CAUTION**
>
> Notice that services are installed one by one. Do not install another service until the installation of the previous one is completed.

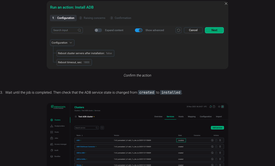
ADB service

1. Open the **Services** tab on the cluster page. Find the row corresponding to the ADB service, click the ⋮ icon in the **Actions** column, and select the **Install ADB** action.



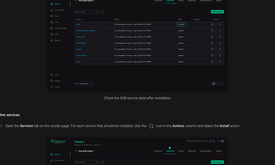
Switch to ADB installation

2. Confirm the action in the window that opens.



Confirm the action

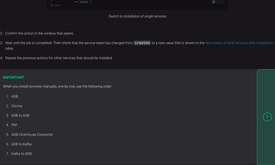
3. Wait until the job is completed. Then check that the ADB service state is changed from `Created` to `Installed`.



Check the ADB service state after installation

Other services

1. Open the **Services** tab on the cluster page. For each service that should be installed, click the ⋮ icon in the **Actions** column and select the **Install** action.



Switch to installation of single services

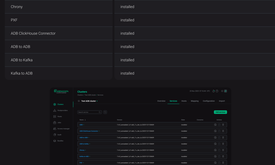
2. Confirm the action in the window that opens.
3. Wait until the job is completed. Then check that the service state has changed from `Created` to a new value that is shown in the New states of ADB services after installation table.
4. Repeat the previous actions for other services that should be installed.

> **IMPORTANT**
>
> When you install services manually, one by one, use the following order:
>
> 1. ADB
> 2. Chrony
> 3. ADB to ADB
> 4. PXF
> 5. ADB Clickhouse Connector
> 6. ADB to Kafka
> 7. Kafka to ADB

Step 3. Check the cluster state after installation

As a result of successful installation, the cluster and its services change their state according to the following rules:

- The cluster state, displayed in the **State** field on the **Clusters** page, is being changed from `Created` to `Installed`.

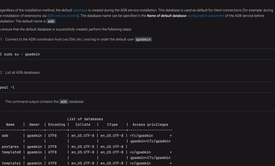


The cluster state after successful installation

- The state of cluster services, displayed on the **Services** tab of the cluster page, is being changed from `Created` to a new value that is shown in the table below.

New states of ADB services after installation

Service	New state
ADB	installed
Chrony	installed
PXF	installed
ADB Clickhouse Connector	installed
ADB to ADB	installed
ADB to Kafka	installed
Kafka to ADB	installed



The state of cluster services after successful installation

Step 4. Check the default database

Regardless of the installation method, the default database is created during the ADB service installation. This database is used as default for client connections (for example, during [testing the connection to ADB](#) or [running queries](#)). The database name can be specified in the **Name of default database** configuration parameter of the ADB service before installation. The default name is `adb`.

To ensure that the default database is successfully created, perform the following steps:

1. Connect to the ADB coordinator host (via SSH, etc.) and log in under the default user `gpadmin`.

```
$ sudo su - gpadmin
```

2. List all ADB databases.

```
psql -l
```

The command output contains the `adb` database:

```
                                  List of databases
   Name    |  Owner  | Encoding |  Collate   |   Ctype    |  Access privileges
-----------+---------+----------+------------+------------+---------------------
 adb       | gpadmin | UTF8     | en_US.UTF-8 | en_US.UTF-8 | =Tc/gpadmin        +
           |         |          |            |            | gpadmin=CTc/gpadmin
 postgres  | gpadmin | UTF8     | en_US.UTF-8 | en_US.UTF-8 |
 template0 | gpadmin | UTF8     | en_US.UTF-8 | en_US.UTF-8 | =c/gpadmin         +
           |         |          |            |            | gpadmin=CTc/gpadmin
 template1 | gpadmin | UTF8     | en_US.UTF-8 | en_US.UTF-8 | =c/gpadmin         +
           |         |          |            |            | gpadmin=CTc/gpadmin
(4 rows)
```

Offline installation

To Table of Contents

This topic describes **offline** installation of ADB. It can be applied to the hosts without access to Internet.

For offline installation, you need to install and configure Arenadata Enterprise Tools (ET). ET is a solution that provides the necessary infrastructure for Arenadata product deployment in environments with limited internet access. The solution is a part of the Arenadata data platform. It provides the repositories necessary for installing and updating the platform components.

The process of offline installation via ADCM includes the following steps.

NOTE

- This function is available only in the Enterprise Edition of ADB.
- This is the only possible installation way for:
  - Arenadata DB Control (ADB Control) — a service that is responsible for monitoring, diagnostics, and queries management in the ADB clusters.
  - Arenadata DB Backup Manager (ADBM) — a service that is responsible for ADB binary backups management.

Step 1.

Install ADCM

Step 2.

Prepare hosts

Step 3.

Install ET cluster

Step 4.

Install ADB cluster

Install ASCM

Contents

Step 1. Check prerequisites
- Software and hardware requirements
- Install docker
- Install docker-compose
- Add firewalld
- Check the ports for container users

Step 2. Install ASCM
- Check the installation container status
- Check the ASCM web interface

Step 3. Update ASCM
- Online update
- Offline update

Table of contents are generated automatically with the `antocr_segment` tag.

This page is for reference only.

Step 1. Check prerequisites

Software and hardware requirements

ASCM is deployed using docker and docker-compose. Docker version 19.03.1+ and docker-compose version 1.24.1+ are required.

- Use one of the following operating systems:
  - RedHat 7.8
  - RedHat 8.1
  - CentOS 7.8
  - CentOS 8.1
  - KY Linux V10
  - NeoKylin V7U6
- Hardware requirements:
  - CPU: 8 cores or more
  - Memory: 16 GB or more
  - Disk: 100 GB or more

It is recommended to use a separate disk to store the docker data directory. For detailed disk partitioning, see Disk partitioning.

Install docker

Install docker 19.03.1+ and start it.

```
yum install -y docker-ce
systemctl start docker
```

Install docker-compose

Install docker-compose 1.24.1+.

```
yum install -y docker-compose
```

Add firewalld

Add firewalld if it is not installed.

```
yum install -y firewalld
```

Start firewalld and set it to start automatically.

```
systemctl start firewalld
systemctl enable firewalld
```

Check the port

Check whether the ports required by ASCM are occupied. If they are occupied, you need to change the port number.

```
netstat -tlnp | grep -E "80|443|8080|8443|9100|9101|9110|9111|9112|9113|9114|9115|9116|9117|9118|9119|9120|9121|9122|9123|9124|9125|9126|9127|9128|9129|9130|9131|9132|9133|9134|9135|9136|9137|9138|9139|9140|9141|9142|9143|9144|9145|9146|9147|9148|9149|9150|9151|9152|9153|9154|9155|9156|9157|9158|9159|9160|9161|9162|9163|9164|9165|9166|9167|9168|9169|9170|9171|9172|9173|9174|9175|9176|9177|9178|9179|9180|9181|9182|9183|9184|9185|9186|9187|9188|9189|9190|9191|9192|9193|9194|9195|9196|9197|9198|9199|9200|9201|9202|9203|9204|9205|9206|9207|9208|9209|9210|9211|9212|9213|9214|9215|9216|9217|9218|9219|9220|9221|9222|9223|9224|9225|9226|9227|9228|9229|9230|9231|9232|9233|9234|9235|9236|9237|9238|9239|9240|9241|9242|9243|9244|9245|9246|9247|9248|9249|9250|9251|9252|9253|9254|9255|9256|9257|9258|9259|9260|9261|9262|9263|9264|9265|9266|9267|9268|9269|9270|9271|9272|9273|9274|9275|9276|9277|9278|9279|9280|9281|9282|9283|9284|9285|9286|9287|9288|9289|9290|9291|9292|9293|9294|9295|9296|9297|9298|9299|9300|9301|9302|9303|9304|9305|9306|9307|9308|9309|9310|9311|9312|9313|9314|9315|9316|9317|9318|9319|9320|9321|9322|9323|9324|9325|9326|9327|9328|9329|9330|9331|9332|9333|9334|9335|9336|9337|9338|9339|9340|9341|9342|9343|9344|9345|9346|9347|9348|9349|9350|9351|9352|9353|9354|9355|9356|9357|9358|9359|9360|9361|9362|9363|9364|9365|9366|9367|9368|9369|9370|9371|9372|9373|9374|9375|9376|9377|9378|9379|9380|9381|9382|9383|9384|9385|9386|9387|9388|9389|9390|9391|9392|9393|9394|9395|9396|9397|9398|9399|9400|9401|9402|9403|9404|9405|9406|9407|9408|9409|9410|9411|9412|9413|9414|9415|9416|9417|9418|9419|9420|9421|9422|9423|9424|9425|9426|9427|9428|9429|9430|9431|9432|9433|9434|9435|9436|9437|9438|9439|9440|9441|9442|9443|9444|9445|9446|9447|9448|9449|9450|9451|9452|9453|9454|9455|9456|9457|9458|9459|9460|9461|9462|9463|9464|9465|9466|9467|9468|9469|9470|9471|9472|9473|9474|9475|9476|9477|9478|9479|9480|9481|9482|9483|9484|9485|9486|9487|9488|9489|9490|9491|9492|9493|9494|9495|9496|9497|9498|9499|9500|9501|9502|9503|9504|9505|9506|9507|9508|9509|9510|9511|9512|9513|9514|9515|9516|9517|9518|9519|9520|9521|9522|9523|9524|9525|9526|9527|9528|9529|9530|9531|9532|9533|9534|9535|9536|9537|9538|9539|9540|9541|9542|9543|9544|9545|9546|9547|9548|9549|9550|9551|9552|9553|9554|9555|9556|9557|9558|9559|9560|9561|9562|9563|9564|9565|9566|9567|9568|9569|9570|9571|9572|9573|9574|9575|9576|9577|9578|9579|9580|9581|9582|9583|9584|9585|9586|9587|9588|9589|9590|9591|9592|9593|9594|9595|9596|9597|9598|9599|9600|9601|9602|9603|9604|9605|9606|9607|9608|9609|9610|9611|9612|9613|9614|9615|9616|9617|9618|9619|9620|9621|9622|9623|9624|9625|9626|9627|9628|9629|9630|9631|9632|9633|9634|9635|9636|9637|9638|9639|9640|9641|9642|9643|9644|9645|9646|9647|9648|9649|9650|9651|9652|9653|9654|9655|9656|9657|9658|9659|9660|9661|9662|9663|9664|9665|9666|9667|9668|9669|9670|9671|9672|9673|9674|9675|9676|9677|9678|9679|9680|9681|9682|9683|9684|9685|9686|9687|9688|9689|9690|9691|9692|9693|9694|9695|9696|9697|9698|9699|9700|9701|9702|9703|9704|9705|9706|9707|9708|9709|9710|9711|9712|9713|9714|9715|9716|9717|9718|9719|9720|9721|9722|9723|9724|9725|9726|9727|9728|9729|9730|9731|9732|9733|9734|9735|9736|9737|9738|9739|9740|9741|9742|9743|9744|9745|9746|9747|9748|9749|9750|9751|9752|9753|9754|9755|9756|9757|9758|9759|9760|9761|9762|9763|9764|9765|9766|9767|9768|9769|9770|9771|9772|9773|9774|9775|9776|9777|9778|9779|9780|9781|9782|9783|9784|9785|9786|9787|9788|9789|9790|9791|9792|9793|9794|9795|9796|9797|9798|9799|9800|9801|9802|9803|9804|9805|9806|9807|9808|9809|9810|9811|9812|9813|9814|9815|9816|9817|9818|9819|9820|9821|9822|9823|9824|9825|9826|9827|9828|9829|9830|9831|9832|9833|9834|9835|9836|9837|9838|9839|9840|9841|9842|9843|9844|9845|9846|9847|9848|9849|9850|9851|9852|9853|9854|9855|9856|9857|9858|9859|9860|9861|9862|9863|9864|9865|9866|9867|9868|9869|9870|9871|9872|9873|9874|9875|9876|9877|9878|9879|9880|9881|9882|9883|9884|9885|9886|9887|9888|9889|9890|9891|9892|9893|9894|9895|9896|9897|9898|9899|9900|9901|9902|9903|9904|9905|9906|9907|9908|9909|9910|9911|9912|9913|9914|9915|9916|9917|9918|9919|9920|9921|9922|9923|9924|9925|9926|9927|9928|9929|9930|9931|9932|9933|9934|9935|9936|9937|9938|9939|9940|9941|9942|9943|9944|9945|9946|9947|9948|9949|9950|9951|9952|9953|9954|9955|9956|9957|9958|9959|9960|9961|9962|9963|9964|9965|9966|9967|9968|9969|9970|9971|9972|9973|9974|9975|9976|9977|9978|9979|9980|9981|9982|9983|9984|9985|9986|9987|9988|9989|9990|9991|9992|9993|9994|9995|9996|9997|9998|9999"
```

Add user

Add a user and set the user password. The user is used to run ASCM. You can also use an existing user.

```
useradd ascm
passwd ascm
```

Add sudo permissions for the user

Add sudo permissions for the user. The following uses the ascm user as an example.

```
sed -i '/^root.*ALL=(ALL).*ALL/a\ascm  ALL=(ALL)  NOPASSWD:SETENV: /data/ascm/*' /etc/sudoers
```

Set the SELINUX

Set SELINUX to permissive mode.

```
setenforce 0
```

Set the limits

Set the limits for the number of files and processes that can be opened by the ascm user.

```
cat >> /etc/security/limits.conf << EOF
ascm soft nofile 65535
ascm hard nofile 65535
ascm soft nproc 65535
ascm hard nproc 65535
EOF
```

Set the kernel parameters

Set the kernel parameters.

```
cat >> /etc/sysctl.conf << EOF
vm.max_map_count = 262144
net.ipv4.ip_forward = 1
EOF
sysctl -p
```

Disable the firewall

Disable the firewall.

```
systemctl stop firewalld
systemctl disable firewalld
```

Disable RX-UX

Disable RX-UX.

```
iptables -P INPUT ACCEPT
iptables -P FORWARD ACCEPT
iptables -P OUTPUT ACCEPT
iptables -t nat -F
iptables -t mangle -F
iptables -F
iptables -X
```

Disable SELinux

Disable SELinux.

```
sed -i 's/SELINUX=enforcing/SELINUX=disabled/g' /etc/selinux/config
```

Step 2. Install ASCM

Install ASCM as the ascm user.

Check the docker container status

Check whether the docker container status is normal. If docker is not started, start docker first.

```
systemctl start docker
```

Check the ASCM port availability

After ASCM is installed, it will start the following ports by default. If these ports are occupied, you need to change the port number.

Port	Description
80	Nginx service port
443	Nginx service port
8080	Nginx service port
8443	Nginx service port
9100	Node service port
9101	Node service port
9110	Node service port
9111	Node service port
9112	Node service port
9113	Node service port
9114	Node service port
9115	Node service port
9116	Node service port
9117	Node service port
9118	Node service port
9119	Node service port
9120	Node service port
9121	Node service port
9122	Node service port
9123	Node service port
9124	Node service port
9125	Node service port
9126	Node service port
9127	Node service port
9128	Node service port
9129	Node service port
9130	Node service port
9131	Node service port
9132	Node service port
9133	Node service port

Switch to the ascm user.

```
su - ascm
```

Create a directory as the installation directory.

```
mkdir -p /data/ascm/
```

Upload the installation package to the installation directory and decompress it.

```
cd /data/ascm/
tar -xvf ascm-installer.tar.gz
```

Run the installation script.

```
./ascmctl install
```

Check the installation container status

Check whether the container status is normal.

```
docker ps -a
```

The output is as follows:

```
CONTAINER ID        IMAGE                                                 COMMAND                  CREATED             STATUS              PORTS               NAMES
ae0c1ae1c7ef        ascm-registry.cn-hangzhou.cr.aliyuncs.com/ascm/ascm   "/usr/bin/supervisord"   2 minutes ago       Up 2 minutes                            ascm-server
```

Check the ASCM web interface

Open the ASCM web interface in a browser. The default port is 8080. The default username and password are admin/Asdfg123.

Login interface

Log in to the ASCM web interface. The following interface is displayed:

Change the password

Set the ASCM URL

Choose Settings > System Settings > Basic Settings. Set the ASCM URL to the IP address or domain name of the server where ASCM is deployed. The default port is 8080. Click Save.

Set the ASCM URL

Click Settings > Agent Settings. Set the ASCM URL to the IP address or domain name of the server where ASCM is deployed. The default port is 8080. Click Save.

Set the ASCM URL

Click Settings > Agent Settings > Agent Installation Settings. Set the ASCM URL to the IP address or domain name of the server where ASCM is deployed. The default port is 8080. Click Save.

Set the ASCM URL

Step 3. Update ASCM

Before updating, it is strongly recommended to back up the database. For details, see Backup and Restore.

1. Log in to the server where ASCM is deployed as the ascm user.
2. Go to the installation path and run the ascmctl update command. The following is an example:

```
./ascmctl update -f ascm-installer.tar.gz
```

Online update

Online update supports the following scenarios:

- Update the docker version.
- Update the docker-compose version.
- Restart the machine where ASCM is deployed.
- Add the environment variable of Nginx for the installation license (Nginx).
- Add the environment variable of Prometheus for the installation license (Prometheus).
  - `PROMETHEUS_EXTRA_ENV_VARS`: Environment variable of Prometheus. For example, `PROMETHEUS_EXTRA_ENV_VARS=GOMAXPROCS=8`.
  - `PROMETHEUS_EXTRA_ARGS`: Startup parameter of Prometheus. For example, `PROMETHEUS_EXTRA_

Prepare hosts

To Table of Contents

To manage a cluster and its nodes via ADCM, it is necessary to prepare hosts for a cluster and link these hosts to ADCM. This is the function of ADCM **hostproviders** — special plugins for ADCM, which encapsulate the complex mechanism of interaction between ADCM and the hosts controlled by it.

ADCM supports several types of hostproviders. For more information on how to configure hostproviders and use them to create hosts, refer to the following documentation:

- SSH
- Yandex Cloud
- VCloud (VMware)
- Cloud.ru Advanced
- CROC Cloud
- ADB Cloud Bundle

For offline installation, the SSH hostprovider is recommended.

CAUTION

Starting with the 6.23.3.44 version, ADB supports both FQDN and short host names. For the previous ADB versions, it is not recommended to use FQDNs (as FQDNs cause errors during the ***Expand*** action and a workaround is needed).

Create a cluster

Daria Barysheva

Contents

To Table of Contents

Step 1. Get the Enterprise version of a cluster bundle

Step 2. Upload a cluster bundle to ADCM

Step 3. Create a cluster based on the uploaded bundle

In ADCM a **cluster** means a set of services running on a set of hosts.

Clusters distributions for ADCM are made in the form of so-called bundles. Generally a bundle is a regular archive that includes a description and software logic of cluster deployment and exploitation.

The steps for adding a cluster to ADCM are listed below.

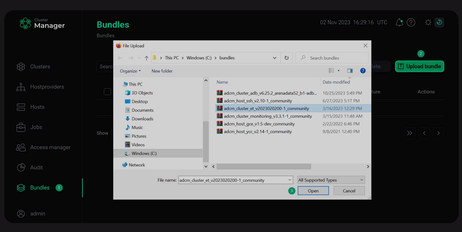
Step 1. Get the Enterprise version of a cluster bundle

Please get a cluster bundle from the Arenadata support team.

Step 2. Upload a cluster bundle to ADCM

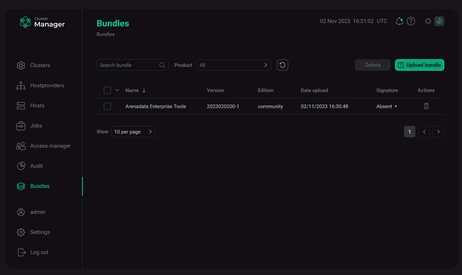
To upload a bundle to ADCM, follow the steps:

1. Select the ***Bundles*** item in the left navigation menu and click ***Upload bundle***.
2. Select a bundle in the Open File Dialog.



Upload a bundle

3. As a result of the performed actions, a bundle is displayed on the ***Bundles*** page.



The result of successful uploading a bundle

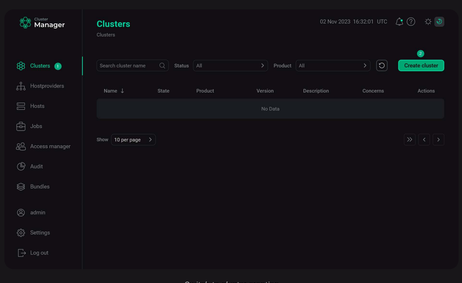
Step 3. Create a cluster based on the uploaded bundle

IMPORTANT

When creating a cluster via the ADCM web interface, you generate a new ADCM cluster instance. It means only adding the cluster to ADCM — at this stage no services are deployed.

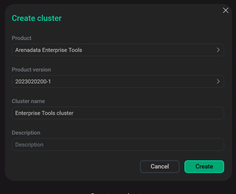
The steps for cluster creation are given below:

1. Select the ***Clusters*** item in the left navigation menu and click ***Create cluster***.



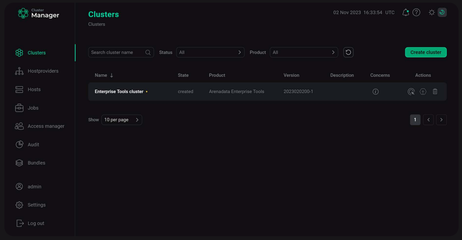
Switch to cluster creation

2. In the opened dialog, describe a new cluster instance:
   - Select an uploaded cluster bundle in the ***Product*** field.
   - Select a bundle version in the ***Product version*** field. Several versions become available in the case of different versions of the same bundle being uploaded.
   - Enter a cluster name in the ***Cluster name*** field.
   - Enter a cluster description in the ***Description*** field if necessary.
   - Set the ***I accept Terms of Agreement*** flag to sign the license agreement. This flag is displayed only for Enterprise bundles. To read the agreement text, refer to the ***Terms of Agreement*** link. You can also sign the license agreement on the ***Bundles*** page by clicking the desired product bundle.
   - Click ***Create***.



Create a cluster

3. As a result, the created cluster instance is displayed on the ***Clusters*** page.



The result of successful cluster creation

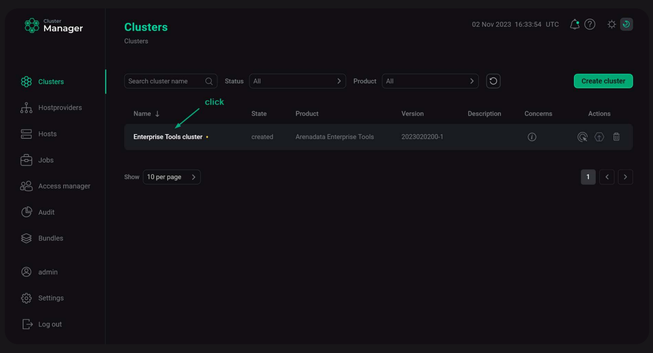
Add services

Daria Barysheva

To Table of Contents

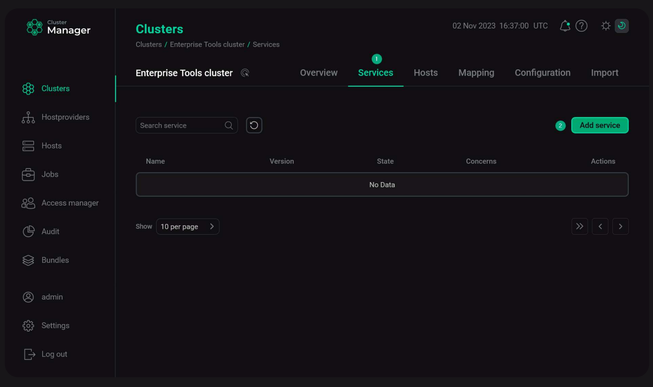
In ADCM a **service** means a software that performs some function. The steps for adding services to a cluster are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



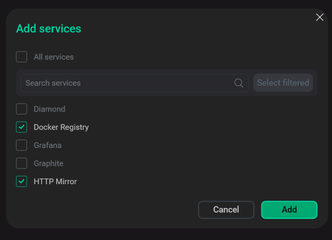
Select a cluster

2. Open the ***Services*** tab on the cluster page and click ***Add service***.



Switch to adding services

3. In the opened dialog, select services that should be added to the cluster and click ***Add***.



Select services

The brief description of available services is listed below.

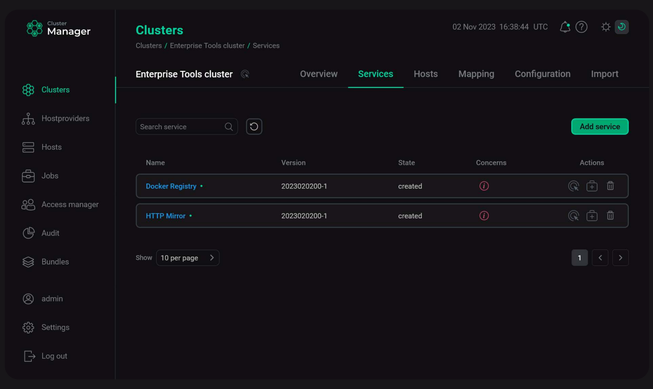
Services that should be added to the Enterprise Tools cluster

Service	Purpose
HTTP Mirror	A service used for hosting packages of the repositories that are needed for offline installation of products
Docker Registry	A service used to store Docker Images that are needed for offline installation of products

NOTE

The CoreDNS service is deprecated — do not select it. The Diamond, Graphite, and Grafana services are used for building monitoring — they will be described separately.

4. As a result, the added services are displayed on the ***Services*** tab.



The result of successful adding services to a cluster

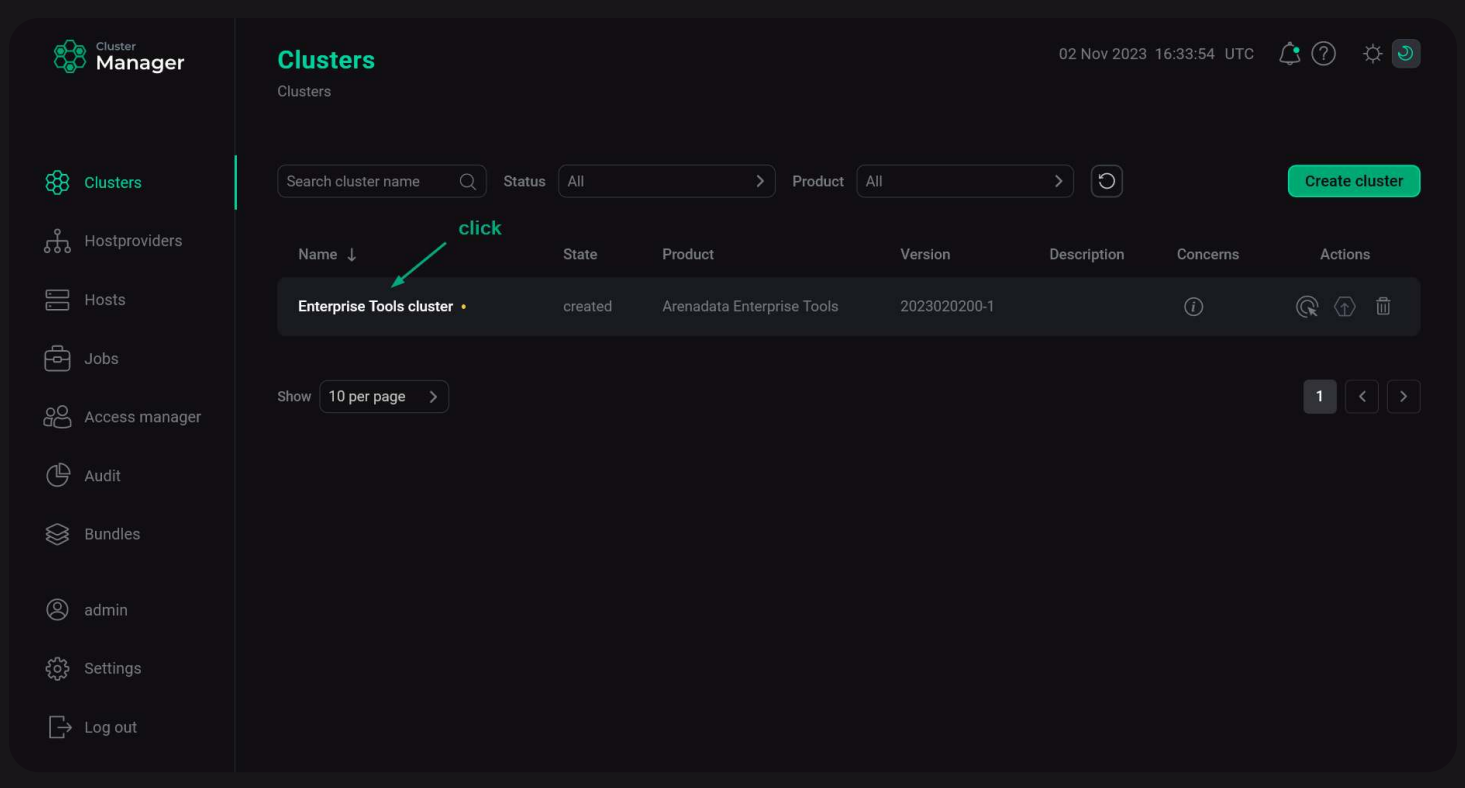
Add hosts to a cluster

Daria Barysheva

To Table of Contents

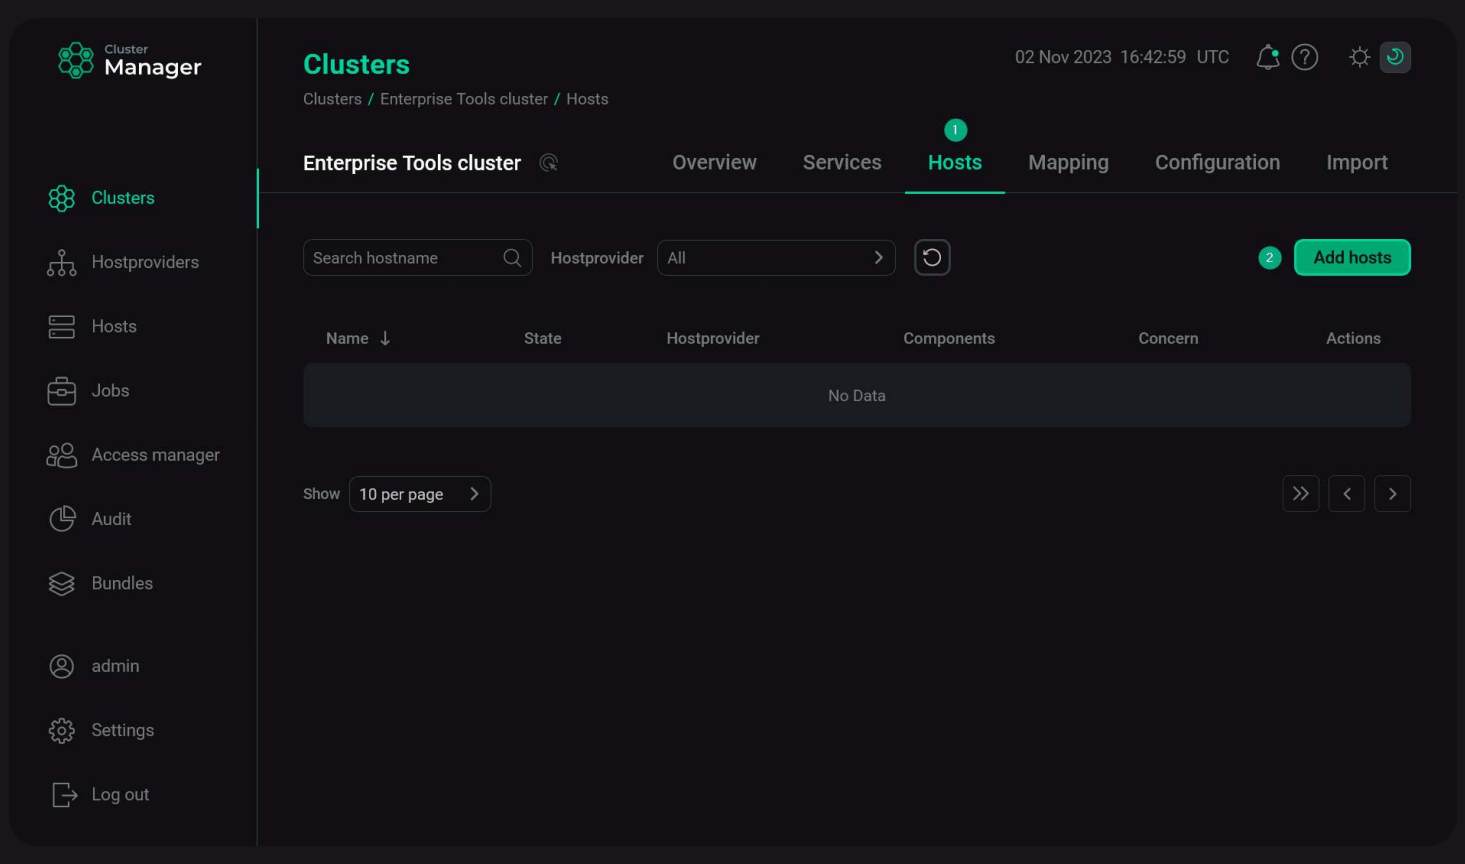
The steps for adding hosts to a cluster are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



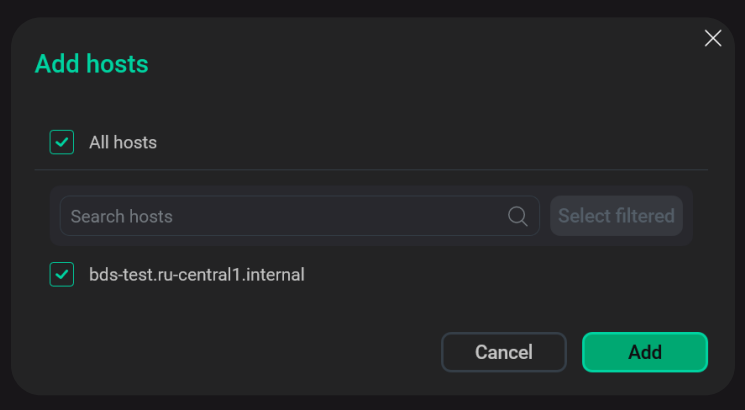
Select a cluster

2. Open the ***Hosts*** tab on the cluster page and click ***Add hosts***.



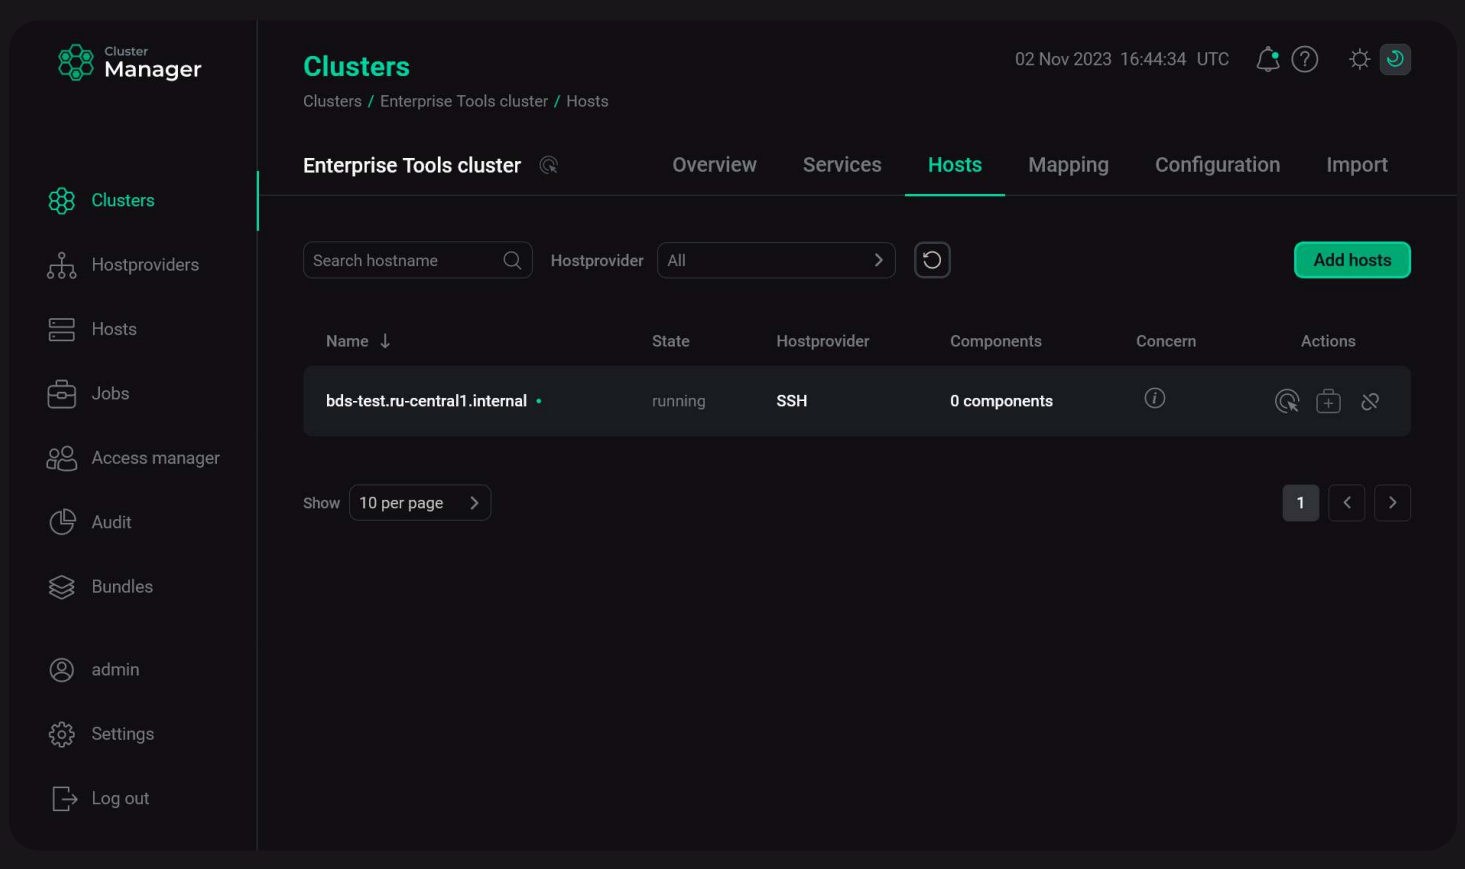
Switch to adding hosts

3. In the opened dialog, select hosts that should be added to the cluster and click ***Add***.



Select hosts

4. As a result, the added hosts are displayed on the ***Hosts*** tab.



The result of successful adding hosts to a cluster

Add components

Daria Barysheva

To Table of Contents

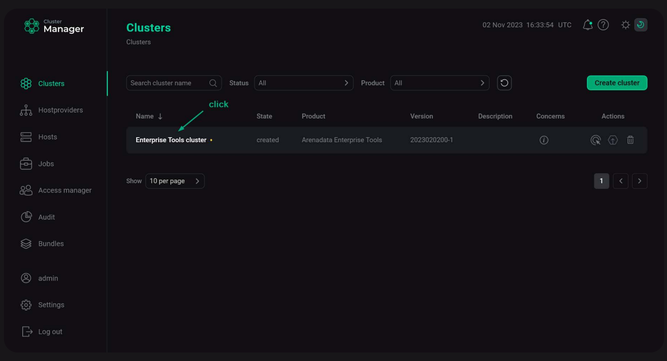
In ADCM a **component** means a part of a service that should be deployed on one or several cluster hosts.

IMPORTANT

Initially, there are no components on any of cluster hosts. You should map components to hosts manually.

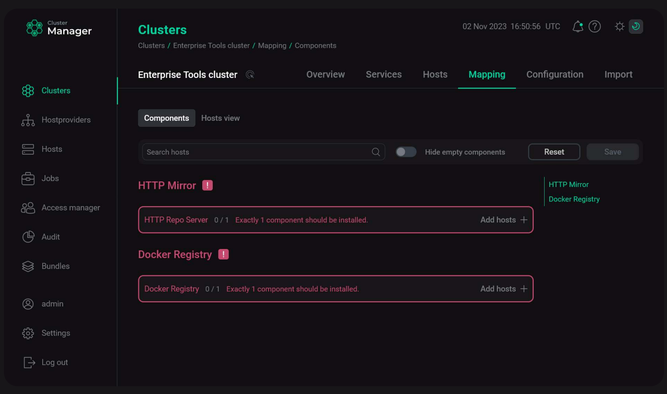
The steps for adding components to hosts are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



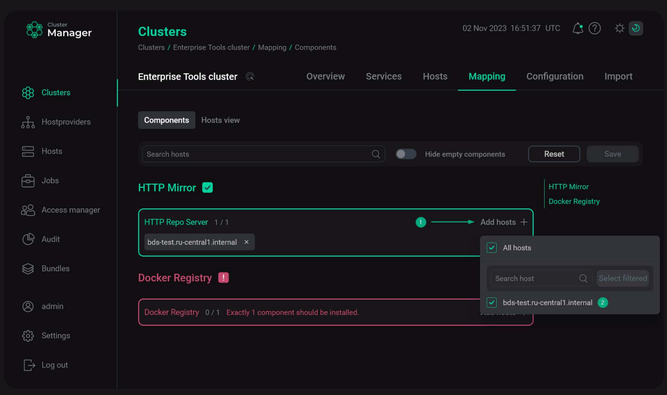
Select a cluster

2. Open the ***Mapping*** tab on the cluster page.



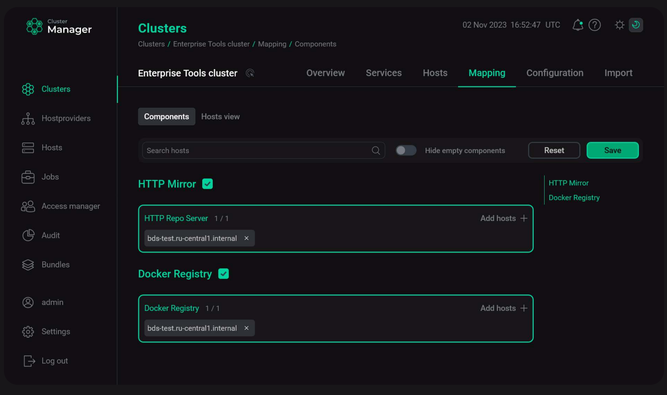
Switch to mapping service components

3. In the window that opens, map components to hosts. To assign hosts for each component, click ***Add hosts*** and select hosts in the pop-up window.



Select hosts for a component

4. After component distribution is completed, click ***Save***.



Save mapping of components

Install a cluster

Daria Barysheva

Contents

To Table of Contents

Step 1. Run installation

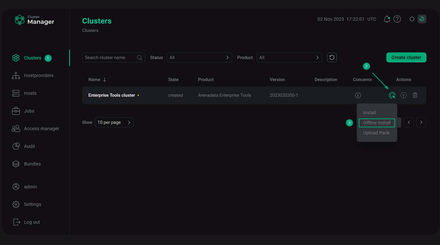
Step 2. Upload packages for offline installation

Step 3. Verify results

Step 1. Run installation

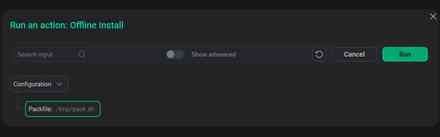
The last step of adding a new Enterprise Tools cluster is to install its services. To do this:

1. Apply the ***Offline Install*** action to the cluster selected on the ***Clusters*** page by clicking the icon in the ***Actions*** column.



Switch to cluster installation

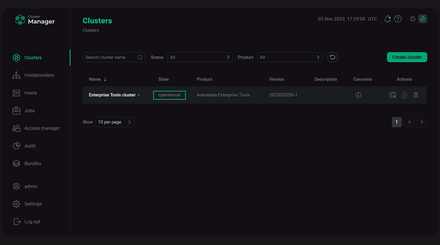
2. In the opened window, enter a full path to the shell script that is received from the Arenadata support team and click ***Run***.



Verify installation

3. Wait until the installation process is completed.

> **NOTE**
>
> In case of errors, you can find logs on the ***Jobs*** page.

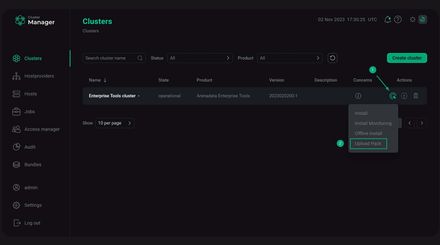


Cluster installation is completed

Step 2. Upload packages for offline installation

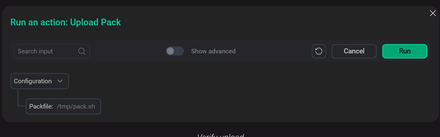
In addition to installing the cluster, you should process the shell script that is received from the Arenadata support team. It is necessary to enable offline installation of products in the future. To do this:

1. Apply the ***Upload Pack*** action to the cluster selected on the ***Clusters*** page by clicking the icon in the ***Actions*** column.



Switch to uploading packages

2. In the opened window, enter a full path to the shell script received from the Arenadata support team and click ***Run***.



Verify upload

3. Wait until the upload process is completed.

> **NOTE**
>
> In case of errors, you can find logs on the ***Jobs*** page.

Step 3. Verify results

The steps for checking the installation results are listed below:

1. Check that ports `443` and `81` are listened at the host where cluster is installed. The first port is used by the Docker Registry service, the second one — by the HTTP Mirror service.

```
$ sudo netstat -ntlp|grep L|grep -E "81|443"
```

The result should look like this:

```
tcp6       0      0 :::443                  :::*                    LISTEN      1694/docker-proxy-c
tcp6       0      0 :::81                   :::*                    LISTEN      1708/docker-proxy-c
```

2. Check that the */opt/arenadata/etools/httprepo/arenadata-repo* folder exists at the host where the cluster is installed. This folder should contain the data necessary for offline installation of the products that you have chosen before getting a shell script from the Arenadata support team.

```
$ ls -la /opt/arenadata/etools/httprepo/arenadata-repo
```

The following example displays the data that can be placed in this folder for ADB installation.

```
total 0
drwxr-xr-x 4 root root 28 Feb 28 17:48 .
drwxr-xr-x 3 root root 28 Feb 28 17:48 ..
drwxr-xr-x 3 root root 32 Feb 28 17:48 ADB
drwxr-xr-x 3 root root 17 Feb 28 17:48 ADM
```

Create a cluster

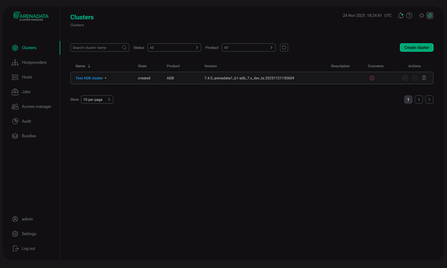
3. As a result, the created cluster instance is displayed on the ***Clusters*** page.



The result of successful cluster creation

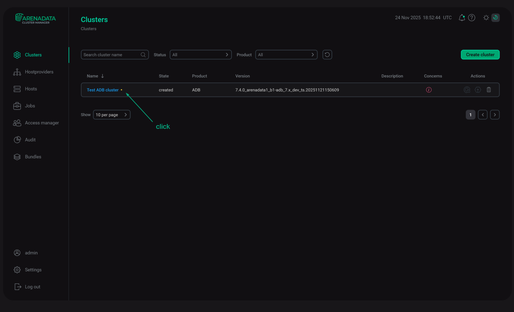
Add services

Daria Barysheva

To Table of Contents

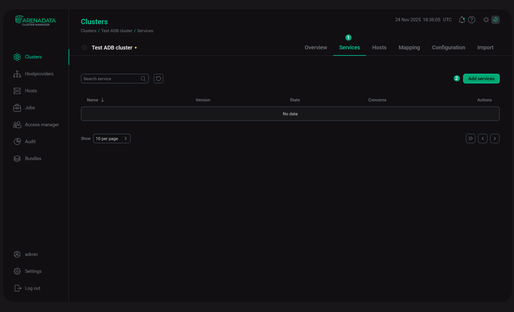
In ADCM a **service** means a software that performs some function. Examples of services for ADB clusters: ADB, ADB Control, Chrony, etc. The steps for adding services to a cluster are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



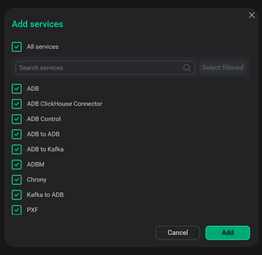
Select a cluster

2. Open the ***Services*** tab on the cluster page and click ***Add service***.



Switch to adding services

3. In the opened dialog, select services that should be added to the cluster and click ***Add***.



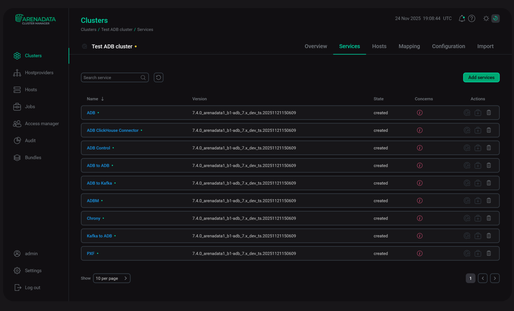
Select services

The brief description of available services is listed below. `CE` means the Common Edition of ADB, `EE` — the Enterprise Edition of ADB.

Services that can be added to the ADB cluster

Service	Mandatory	Edition	Purpose
ADB	Yes	CE/EE	A core service, corresponding to the massively parallel DBMS based on Greengage DB
Chrony	No	CE/EE	A time service. Provides time synchronization for the cluster hosts, that is necessary for the cluster to work correctly. If the time service is already configured on the hosts, there is no need to install Chrony
PXF	No	CE/EE	A service that provides ADB interactions with external data sources
ADB ClickHouse Connector	No	EE	ADB ClickHouse Connector — a service that provides two-way ADB interactions with ClickHouse. Requires PXF
ADB to Kafka	No	EE	ADB to Kafka Connector — a service that provides one-way ADB interactions with Kafka. Requires PXF
Kafka to ADB	No	EE	Kafka to ADB Connector — a service that provides one-way Kafka interactions with ADB
ADB to ADB	No	EE	ADB to ADB Connector — a service that provides two-way interactions between ADB clusters
ADBM	No	EE	Arenadata DB Backup Manager — a service for ADB binary backups management. Can be installed only offline
ADB Control	No	EE	Arenadata DB Control (ADB Control) — a service for monitoring, diagnostics, and management of queries, that run in the ADB cluster. Can be installed only offline

4. As a result, the added services are displayed on the ***Services*** tab.



The result of successful adding services to a cluster

NOTE

You can also add services later. The process of adding new services to already running cluster does not differ from installing a service from scratch.

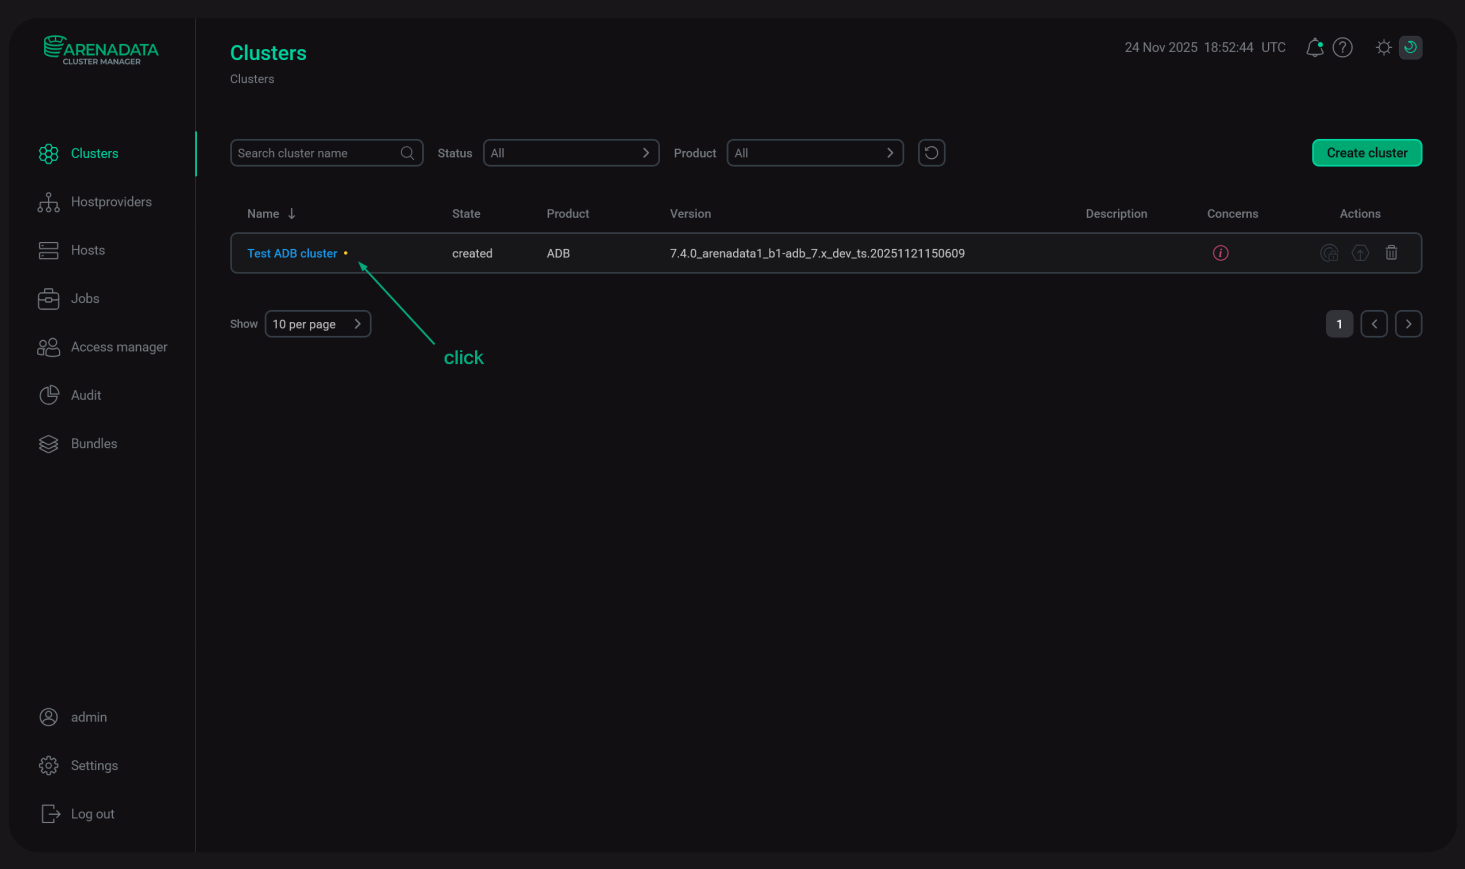
Add hosts to a cluster

Daria Barysheva

To Table of Contents

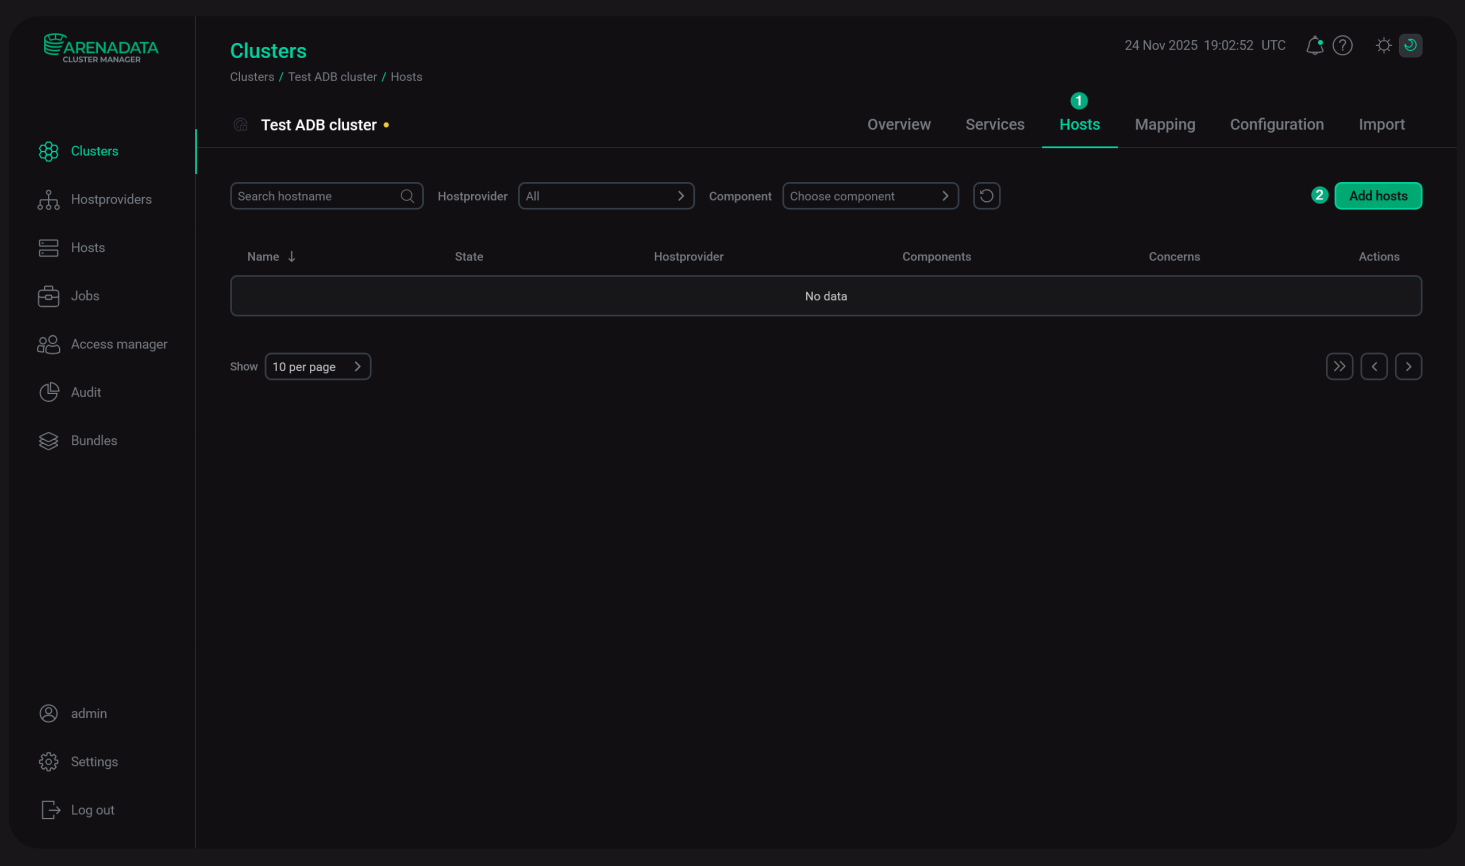
The steps for adding hosts to a cluster are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



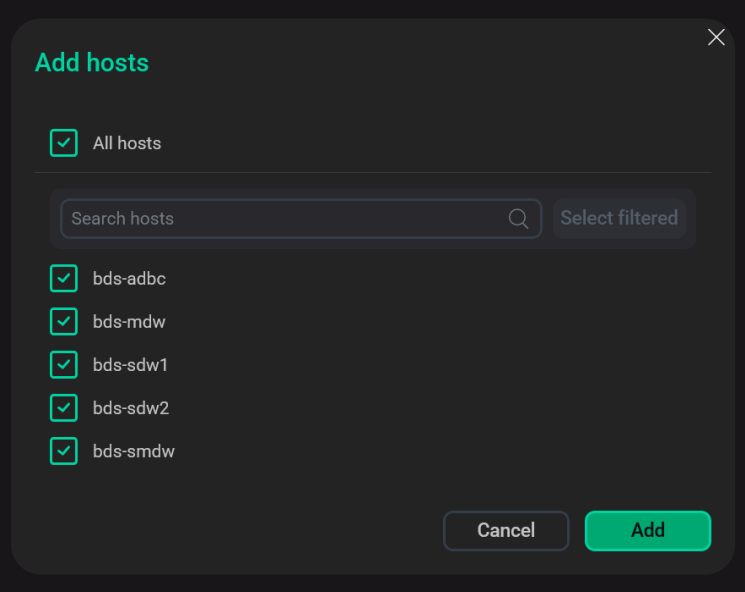
Select a cluster

2. Open the ***Hosts*** tab on the cluster page and click ***Add hosts***.



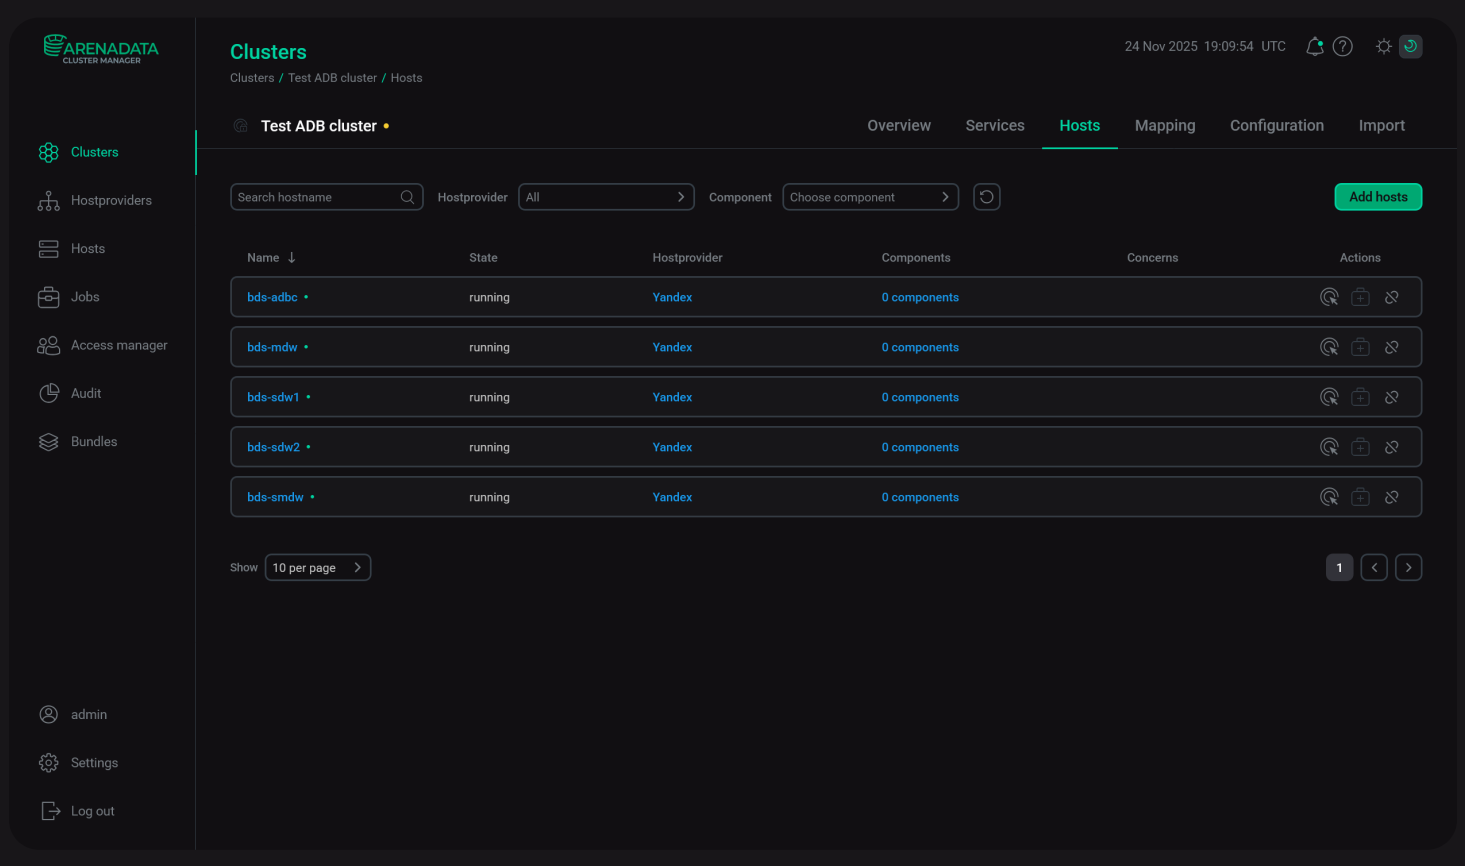
Switch to adding hosts

3. In the opened dialog, select hosts that should be added to the cluster and click ***Add***.



Select hosts

4. As a result, the added hosts are displayed on the ***Hosts*** tab.



The result of successful adding hosts to a cluster

Add components

Daria Borysheva

To Table of Contents

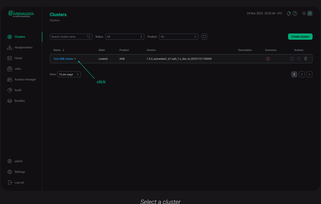
In ADCM a **component** means a part of a service that should be deployed on one or several cluster hosts. For example, ADB service consists of such components as ADB Master, ADB Segment, ADB Standby, etc.

IMPORTANT

Initially, there are no components on any of cluster hosts. You should map components to hosts manually.

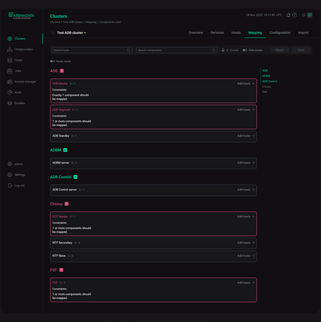
The steps for adding components to hosts are listed below:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



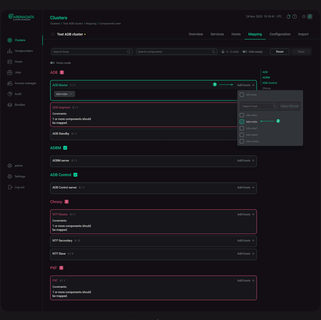
Select a cluster

2. Open the ***Mapping*** tab on the cluster page.



Switch to mapping service components

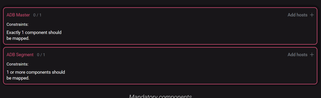
3. In the window that opens, map components to hosts. To assign hosts for each component, click ***Add hosts*** and select hosts in the pop-up window.



Select hosts for a component

Mandatory components

Each service can have mandatory and optional components. Mandatory components are highlighted in red. The ADCM UI also displays how many mandatory components should be installed.



Mandatory components

CAUTION

Without assigning a necessary number of hosts to mandatory components, the component mapping cannot be saved.

The typical scheme of mapping components in ADB clusters is described in the table below. It is based on the Enterprise Edition of ADB.

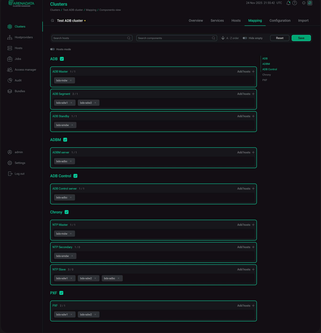
Example of mapping ADB components to hosts

Host	Service	Component	Notes
Coordinator host	ADB	ADB Master	Should be installed on the coordinator host
	Chrony	NTP Master	Should be installed on the coordinator host
Secondary Master Host (Standby)	ADB	ADB Standby	Should be installed on the standby coordinator host
	Chrony	NTP Secondary	Should be installed on the standby coordinator host
Segment host (1..N)	ADB	ADB Segment	Should be installed on each segment host
	Chrony	NTP Slave	Should be installed on each segment host
	PXF	PXF	Should be installed on one or more segment hosts and, optionally, on the coordinator host
ADB Control/ADBM host	ADB Control	ADB Control server	It is recommended to use a separate host for this component
	ADBM	ADBM server	Can be installed on the same host with ADB Control server
	Chrony	NTP Slave	Should be installed on the ADB Control/ADBM host

CAUTION

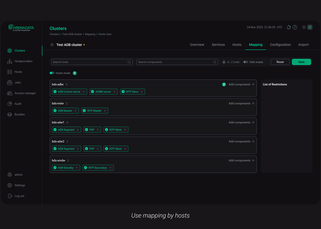
Do not install ADB Control server or ADBM server on the same host with the ADB Master or ADB Segment components. This feature is reserved for informational purposes only. Use a separate host for these components.

4. After component distribution is completed, click ***Save***



Save mapping of components

Starting with ADCM 2.2.0, you can use another mapping mode — by hosts. To do this, switch on the ***Hosts mode*** toggle and map components to hosts by clicking ***Add components*** for each host sequentially.



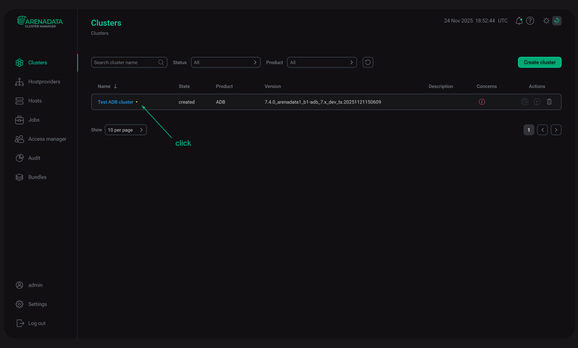
Use mapping by hosts

Configure services

Daria Barysheva

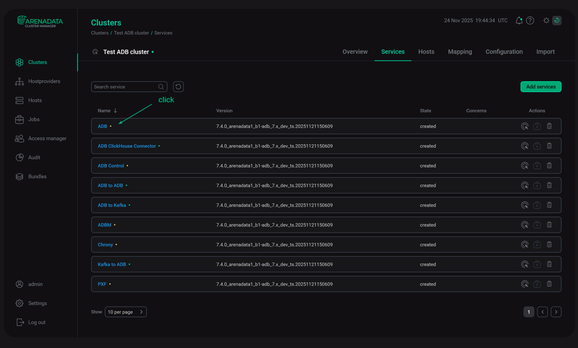
To Table of Contents

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.



Select a cluster

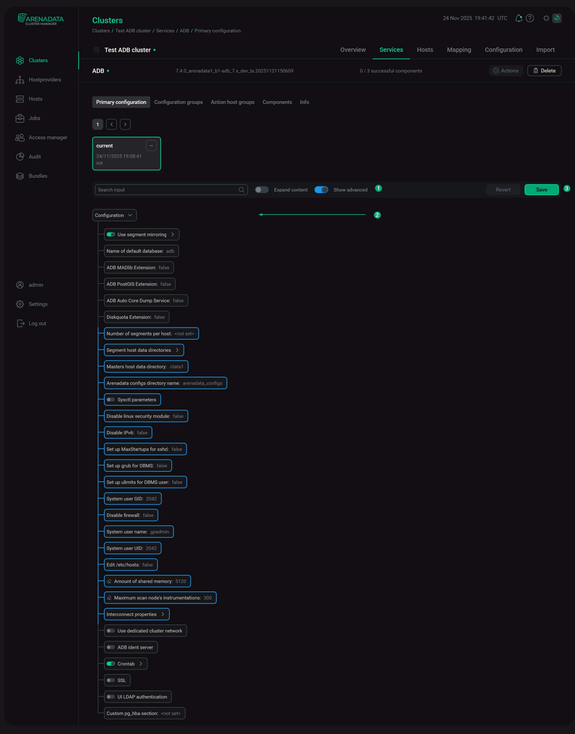
2. Open the ***Services*** tab on the cluster page, find the row that contains the desired service, and click its name in the ***Name*** column.



Switch to configuring a service

3. In the window that opens:

   - Open the ***Primary Configuration*** tab.
   - Switch on the ***Show advanced*** toggle.
   - Fill in configuration parameters of the selected service. The fields highlighted in red are mandatory.
   - Click ***Save***.



Configure a service

Pay attention to the following parameters:

- ***ADB → Edit /etc/hosts***. Set to `true` to let ADB modify the */etc/hosts* file to include hostnames of all cluster hosts. Otherwise, you should modify this file manually or configure a DNS server. Using the ADB service settings, you can also adjust other parameters of the cluster hosts to align them with recommended values.
- ***ADB → Disable linux security module*** and ***ADB → Set up GRUB for DBMS***. Changing these parameters requires host reboot, so it is recommended to set them to `true` before cluster installation and then set ***Reboot cluster servers after installation*** to `true` when launching the Install cluster action to reboot hosts automatically. If you change these parameters after installation, you will have to stop the cluster and reboot hosts manually.
- ***Chrony → NTP servers***. Though this parameter is optional, we recommend to set it to the nearest NTP server, e.g. the one that your company uses.

NOTE

- For more information about services configuration parameters, see Configuration parameters.
- If you plan to use external databases for ADB Control and/or ADBM, you need to perform additional configuration steps before installation of these services:
  - ADB Control
  - ADBM

Configure a cluster

Key concepts

Contents

To Table of Contents

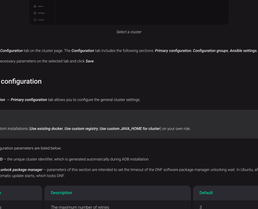
Primary configuration
Configuration groups
Ansible settings

IMPORTANT

There is usually no need to change cluster configuration parameters. You can leave all parameters at the default values.

After creation a new cluster, you can configure it by performing the following steps:

1. Select a cluster on the **Clusters** page. To do this, click a cluster name in the **Name** column.



Select a cluster

2. Open the **Configuration** tab on the cluster page. The **Configuration** tab includes the following sections: *Primary configuration*, *Configuration groups*, *Ansible settings*.
3. Fill in all necessary parameters on the selected tab and click **Save**.

Primary configuration

The *Configuration → Primary configuration* tab allows you to configure the general cluster settings.

CAUTION

Use all custom installations (*Use existing docker*, *Use custom registry*, *Use custom JAVA_HOME for cluster*) on your own risk.

Available configuration parameters are listed below:

- *Cluster UUID* – the unique cluster identifier, which is generated automatically during ADB installation.
- *Timeout to unlock package manager* – parameters in this section are intended to set the timeout of the DNF software package manager unlocking wait. In Ubuntu, after the host reboot, automatic update starts, which locks DNF.

Name	Description	Default
retries	The maximum number of retries	3
delay	The time delay between retries (in seconds)	10

- Paths to the repositories that are used during the installation process depending on the cluster operating system (AltLinux, Astra Linux, RED OS, and Ubuntu). Only the marked repositories are registered on the cluster hosts.

Altlinux 10 repositories

Parameter	Description
Set up Arenadata repo	Whether or not to use the repository that is described in the field *Arenadata repo url*
Arenadata repo url	The repository that is required to install ADB
Set up custom Arenadata enterprise repo	Whether or not to use the repository that is described in the field *Custom Arenadata enterprise repo*
Custom Arenadata enterprise repo	Custom Arenadata Enterprise repository. If not filled in, the default repository will be used
Set up ADB monitoring repo	Whether or not to use the repository that is described in the field *prometheus_repo* (for future use)
prometheus_repo	The repository that is required to install monitoring (for future use)

Astra linux repositories

Parameter	Description
Set up Arenadata repo	Whether or not to use the repository that is described in the field *Arenadata repo url*
Arenadata repo url	The repository that is required to install ADB
Set up custom Arenadata enterprise repo	Whether or not to use the repository that is described in the field *Custom Arenadata enterprise repo*
Custom Arenadata enterprise repo	Custom Arenadata Enterprise repository. If not filled in, the default repository will be used
Set up ADB monitoring repo	Whether or not to use the repository that is described in the field *prometheus_repo* (for future use)
prometheus_repo	The repository that is required to install monitoring (for future use)

redos 7 repositories

Parameter	Description
Set up Arenadata repo	Whether or not to use the repository that is described in the field *Arenadata repo url*
Arenadata repo url	The repository that is required to install ADB
Set up custom Arenadata enterprise repo	Whether or not to use the repository that is described in the field *Custom Arenadata enterprise repo*
Custom Arenadata enterprise repo	Custom Arenadata Enterprise repository. If not filled in, the default repository will be used
Set up ADB monitoring repo	Whether or not to use the repository that is described in the field *prometheus_repo* (for future use)
prometheus_repo	The repository that is required to install monitoring (for future use)

Ubuntu 22.04 repositories

Parameter	Description
Set up Arenadata repo	Whether or not to use the repository that is described in the field *Arenadata repo url*
Arenadata repo url	The repository that is required to install ADB
Set up custom Arenadata enterprise repo	Whether or not to use the repository that is described in the field *Custom Arenadata enterprise repo*
Custom Arenadata enterprise repo	Custom Arenadata Enterprise repository. If not filled in, the default repository will be used
Set up ADB monitoring repo	Whether or not to use the repository that is described in the field *prometheus_repo* (for future use)
prometheus_repo	The repository that is required to install monitoring (for future use)

- *Use existing docker* – a flag that indicates whether to use the existing Docker during the installation of ADB services (e.g. ADB Control, ADBM, Monitoring, Enterprise Tools). If this flag is set, only containers will be deployed, while Docker and Docker Compose installation will be skipped. For more information on Docker requirements, see *Software requirements*.

IMPORTANT

Starting with ADB [7.1.0](), ADB Control rewrites Docker settings in the */etc/docker/daemon.json* file for security purposes. Thus, if you need to modify this file, set the *Use existing docker* option when configuring ADB. This option will also allow you to use Docker in the rootless mode.

- *Use custom registry* – a switcher that determines whether to use a custom registry. When the switcher is activated, the following parameters are available.

Parameter	Description
registry	A custom registry URL in the following form: `<host>:<port>`
prefix	An optional subdirectory name that will be added to the custom registry URL: `<registry>/<prefix>`
Use self-signed certificate	Whether or not to use a self-signed certificate
Self-signed certificate	A self-signed certificate text

Ubuntu

/usr/lib/jvm/java-17-openjdk-amd64

RED OS

/usr/lib/jvm/jre-17-openjdk

ASLinux

/usr/lib/jvm/jre-17

IMPORTANT

- If you plan to use custom Java (such as Azul), Java 17 is required for installation.
- For Astra Linux, the *JAVA_HOME* field is mandatory starting with ADB [6.17.1-36]().

- *Parameter archiving* – a switcher that indicates whether to export ADB settings according to the specified schedule. When the switcher is activated, the *Parameter archiving job* settings field becomes available. Enter a schedule for an export job in that field. The field value should be a valid [cron]() expression. After you edit and save the *Parameter archiving job setting* option, run the cluster action *Reconfigure parameter archiving*.
  Each time a [cron]() job is run, ADB settings are exported to the following directory:

```
/home/gpadmin/arenadata_configs/settings/<timestamp>
```

  where `<timestamp>` is a timestamp of the export job in the `YYYY-MM-DD_HH-mm-ss` format.
  A job execution log is saved to the parameter_archiving.log file.
  Currently, the following settings are offloaded.

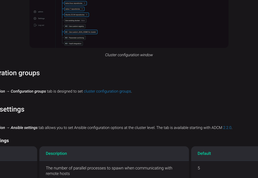
Service	Exported parameters	Relative path
ADB	GUC values for coordinator/segment	/YYYY-MM-DD_HH-mm-ss/_guc_config.json
	Linux Greenplum-related parameters that are exported from etc/sysctl.conf	/YYYY-MM-DD_HH-mm-ss/_sc_config.json
	Resource group parameters	/YYYY-MM-DD_HH-mm-ss/_rg_config.json
ADB Control	Configuration parameters of ADB Control components	/adcs/*
ADBM	Configuration parameters of ADBM components	/adbm/*
PXF	PXF settings that are exported from: - */etc/pxf/conf/pxf-application.properties* - */etc/pxf/conf/pxf-profiles.xml* - *$PXF_BASE/servers/**	/pxf_config/*

- *Vault integration* – a switcher that indicates whether to use HashiCorp Vault to store secrets of ADB services. When the switcher is activated, the following parameters become available.

Name	Description	Default
Address of the Vault server	The Vault server address (e.g. `172.168.1.120` or `vault.domain.com`). Required only if the *Writer authentication method for the Vault server* parameter is set to `token`	–
Port of the Vault server	The Vault server port. Should be specified if the service is published on a port other than HTTPS (443)	443
Internal CA certificate in PEM format (optional)	The internal CA certificate in PEM format that signed the Vault server's certificate	–
Use PEM CA for vault	Defines whether to use the CA certificate in PEM format. If you set this parameter to `true`, you also need to fill in *Internal CA certificate in PEM format (optional)*. Format the multiline plaintext in vault, set *Use PEM CA for vault* to `true`	false
Vault namespace (optional)	The Vault namespace	–
Writer authentication method for the Vault server	The authentication method that is used to connect to the Vault server with write access. Possible values: - `token` - `approle`	approle
Writer Vault token	The application token that is used to connect to the Vault server with write access. Required only if the *Writer authentication method for the Vault server* parameter is set to `token`	–
Writer Vault role ID	The role identifier provided for applications to connect to the Vault server with write access. Required only if the *Writer authentication method for the Vault server* parameter is set to `approle`	–
Writer Vault secret ID	The secret identifier associated with the *Writer Vault role ID* role that is used by applications to connect to the Vault server with write access. Required only if the *Writer authentication method for the Vault server* parameter is set to `approle`	–
Reader authentication method for the Vault server	The authentication method that is used to connect to the Vault server with read access. Possible values: - `token` - `approle`	approle
Reader Vault token	The application token that is used to connect to the Vault server with read access. Required only if the *Reader authentication method for the Vault server* parameter is set to `token`	–
Reader Vault role ID	The role identifier provided for applications to connect to the Vault server with read access. Required only if the *Reader authentication method for the Vault server* parameter is set to `approle`	–
Reader Vault secret ID	The secret identifier associated with the *Reader Vault role ID* role that is used by applications to connect to the Vault server with read access. Required only if the *Reader authentication method for the Vault server* parameter is set to `approle`	–
Mount point for ADB cluster secrets	A mount point that is accessible for read/write operations with the provided ADB cluster authentication parameters. Each service will store secrets on the Vault server at the following path: *<Mount point for ADB cluster>/arenadata/<cluster_name>/service/<service_name>/<component>*	–
Login mount point	A custom authentication mount point. If empty, equals to the authentication method selected in the *Writer authentication method for the Vault server* (write) or *Reader authentication method for the Vault server* (read) field	–

IMPORTANT

- Before editing Vault integration parameters, ensure that Vault is installed and configured.
- Each time you edit and save parameters in the **Vault integration** section, run the cluster action *Reconfigure Vault integration*.
- Currently, Vault can be used to store authentication parameters of ADB Control and ADBM.
- If you need to store credentials for the ADB Control Query DB and Metrics DB in Vault, set up these databases as *external*.



Cluster configuration window

Configuration groups

The *Configuration → Configuration groups* tab is designed to set *cluster configuration groups*.

Ansible settings

The *Configuration → Ansible settings* tab allows you to set Ansible configuration options at the cluster level. The tab is available starting with ADCM [2.0]().

Ansible settings

Name	Description	Default
forks	The number of parallel processes to spawn when communicating with remote hosts	5

Import ET settings

Daria Barysheva

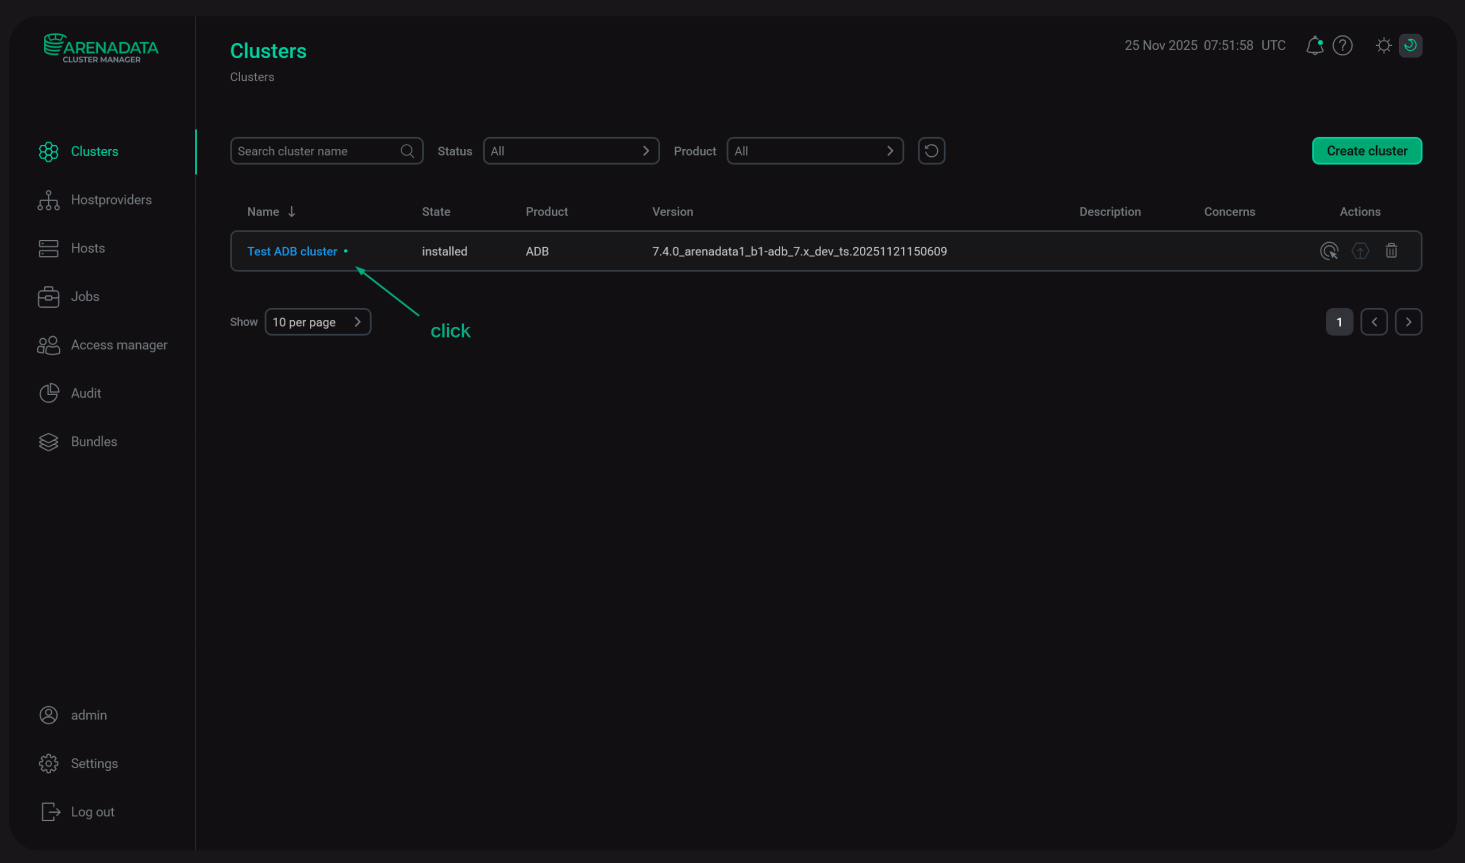
To Table of Contents

IMPORTANT

This step should be performed only in the case of offline installation.

In order to determine that a new cluster should be installed offline, it is necessary to integrate it with the previously created Enterprise Tools (ET) cluster. Follow the steps:

1. Select a cluster on the ***Clusters*** page. To do this, click a cluster name in the ***Name*** column.

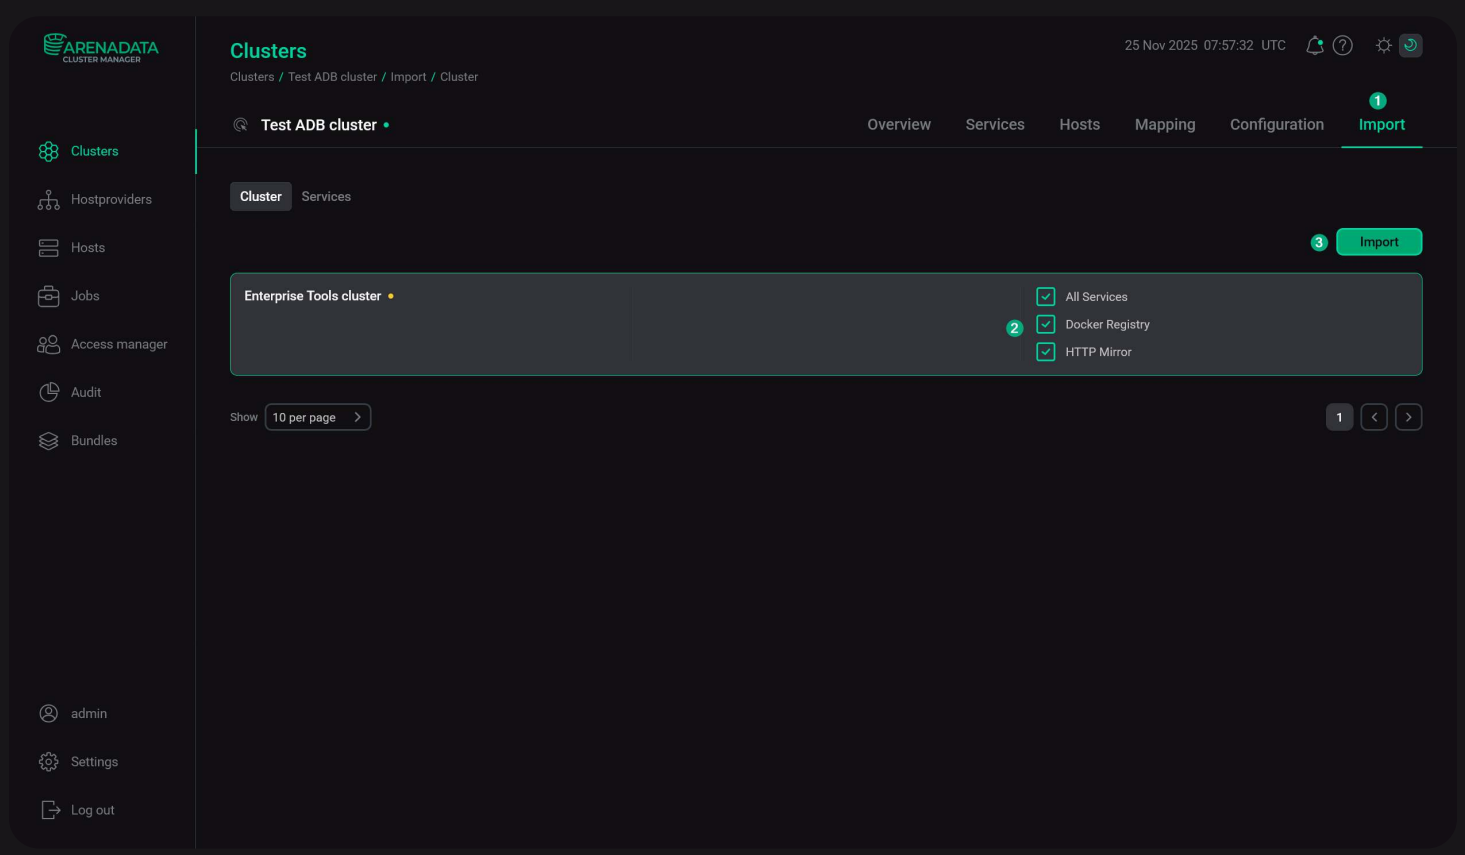


Select a cluster

2. Open the ***Import*** tab in the cluster menu.

3. Select ***Docker Registry*** and ***HTTP Mirror*** services of the previously created ET cluster.

4. Click ***Import***.



Integration with a ET cluster

NOTE

After successful import, the data stored locally in the Enterprise Tools cluster can be used at the cluster installation stage. So there is no need to extract this data via Internet.

Install a cluster

Time reading: 9 min

Contents

To Table of Contents

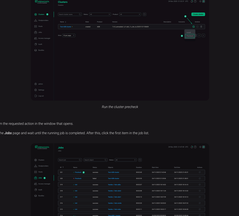
Step 1. Precheck
Step 2. Run installation
- Whole cluster
- Single services

Step 3. Check the cluster state after installation
Step 4. Check the default database

Step 1. Precheck

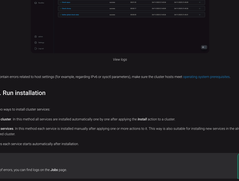
Before installing a new cluster it is recommended to run the **Precheck** action. By doing this, you make sure that all necessary repositories are available, the cluster does not contain hosts with the same IP addresses, and all other prerequisites are met. Do the following:

1. Apply the **Precheck** action to the cluster selected on the **Clusters** page by clicking the icon in the **Actions** column.



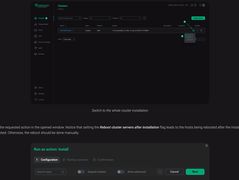
Run the cluster precheck

2. Confirm the requested action in the window that opens.
3. Open the **Jobs** page and wait until the running job is completed. After this, click the first item in the job list.



View jobs

4. View logs in the window that opens. To download logs, click **Download**.



View logs

If the logs contain errors related to host settings (for example, regarding IPv4 or sysctl parameters), make sure the cluster hosts meet operating system prerequisites.

Step 2. Run installation

There are two ways to install cluster services:

1. **Whole cluster** – in this method all services are installed automatically one by one after applying the **Install** action to a cluster.
2. **Single services** – in this method each service is installed manually after applying one or more actions to it. This way is also suitable for installing new services in the already deployed cluster.

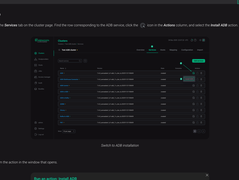
In both cases each service starts automatically after installation.

> **NOTE**
>
> In case of errors, you can find logs on the **Jobs** page.

Whole cluster

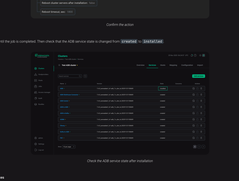
To install all cluster services within a single action, follow the steps:

1. Apply the **Install** action to the cluster selected on the **Clusters** page by clicking the icon in the **Actions** column.



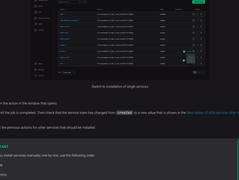
Switch to the whole cluster installation

2. Verify the requested action in the opened window. Notice that setting the **Reboot cluster servers after installation** flag leads to the hosts being rebooted after the installation is completed. Otherwise, this should be done manually.



Confirm the action

3. Wait until the job is completed.
4. If some services fails during installation, but the preceding services are installed successfully, you can try to fix errors and restart installation of all failed services. To do this, select the **Reinstall** action in the **Actions** column on the **Clusters** page.



Installation restart

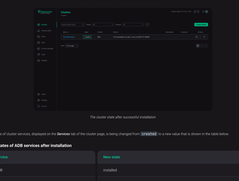
Single services

To install one or several cluster services manually, add these services to the cluster and then perform the actions described in the following subsections. The process of installing the ADB service differs from all other services.

> **CAUTION**
>
> Notice that services are installed one by one. Do not install another service until the installation of the previous one is completed.

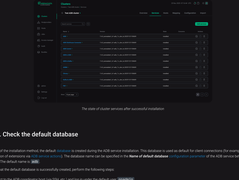
ADB service

1. Open the **Services** tab on the cluster page. Find the row corresponding to the ADB service, click the icon in the **Actions** column, and select the **Install ADB** action.



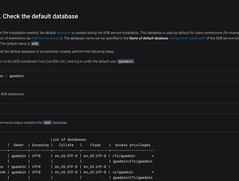
Switch to ADB installation

2. Confirm the action in the window that opens.



Confirm the action

3. Wait until the job is completed. Then check that the ADB service state is changed from `Installed` to `InitialCmd`.



Check the ADB service state after installation

Other services

1. Open the **Services** tab on the cluster page. For each service that should be installed, click the icon in the **Actions** column and select the **Install** action.

Switch to installation of single services

2. Confirm the action in the window that opens.
3. Wait until the job is completed. Then check that the service state has changed from `Installed` to a new value that is shown in the New states of ADB services after installation table.
4. Repeat the previous actions for other services that should be installed.

> **IMPORTANT**
>
> When you install services manually, one by one, use the following order:
>
> 1. ADB
> 2. Chrony
> 3. ADB to ADB
> 4. PXF
> 5. ADB Clickhouse Connector
> 6. ADB to Kafka
> 7. Kafka to ADB
> 8. ADB Control
> 9. ADBM

Step 3. Check the cluster state after installation

As a result of successful installation, the cluster and its services change their state according to the following rules:

- The cluster state, displayed in the **Dom** field on the **Clusters** page, is being changed from `Installed` to `UnInstalled`.

The cluster state after successful installation

- The state of cluster services, displayed on the **Services** tab of the cluster page, is being changed from `Installed` to a new value that is shown in the table below.

New states of ADB services after installation

Service	New state
ADB	installed
Chrony	installed
PXF	installed
ADB Clickhouse Connector	installed
ADB to ADB	installed
ADB to Kafka	installed
Kafka to ADB	installed
ADB Control	installed
ADBM	installed

The state of cluster services after successful installation

Step 4. Check the default database

Regardless of the installation method, the default database is created during the ADB service installation. This database is used as default for client connections (for example, during the installation of extensions via the command utility). The database name can be specified in the **Name of default database** configuration parameter of the ADB service before installation. The default name is `adb`.

To ensure that the default database is successfully created, perform the following steps:

1. Connect to the ADB coordinator host (via SSH, etc.) and log in under the default user `gpadmin`:

```
$ sudo su - gpadmin
```

2. List all ADB databases.

The command output contains the `adb` database:

```
                                  List of databases
    Name     |  Owner   | Encoding |  Collate   |   Ctype    |  Access privileges
-------------+----------+----------+------------+------------+---------------------
adb          | gpadmin  | UTF8     | en_US.UTF-8 | en_US.UTF-8 | =Tc/gpadmin        +
             |          |          |            |            | gpadmin=CTc/gpadmin
postgres     | gpadmin  | UTF8     | en_US.UTF-8 | en_US.UTF-8 |
template0    | gpadmin  | UTF8     | en_US.UTF-8 | en_US.UTF-8 | =c/gpadmin         +
             |          |          |            |            | gpadmin=CTc/gpadmin
template1    | gpadmin  | UTF8     | en_US.UTF-8 | en_US.UTF-8 | =c/gpadmin         +
             |          |          |            |            | gpadmin=CTc/gpadmin
(4 rows)
```

LDAP authentication in ADB

Daria Barysheva

Contents

Configure LDAP authentication
Synchronize ADB and LDAP
Check LDAP authentication

ADB (as well as Greenplum) supports *Lightweight Directory Access Protocol (LDAP)* user authentication. When LDAP authentication is used, user accounts and passwords are checked on the selected LDAP server. The steps for configuring LDAP authentication in ADB via ADCM are described below.

Configure LDAP authentication

To configure LDAP authentication in ADB, follow the steps:

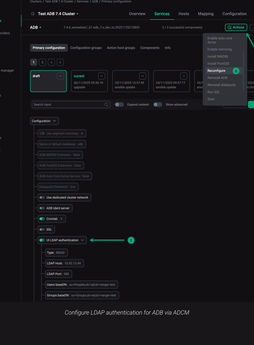
1. Ensure the target LDAP server is configured and available. ADB supports two LDAP implementations: Microsoft Active Directory (MS AD) and 389 Directory server as a part of FreeIPA.
2. Open the ADB service configuration page in ADCM.
3. Switch on the ***UI LDAP authentication*** toggle.
4. Fill in the following fields.

Field	Description	Default value	Example in MS AD
Type	A type of the LDAP server. Possible values: ▪ `MSAD` — Microsoft Active Directory; ▪ `FreeIPA` — 389 Directory server as a part of FreeIPA.	MSAD	MSAD
LDAP Host	A domain name or an IPv4 address of the LDAP server	—	10.92.12.49
LDAP Port	A port number on the LDAP server to connect to	—	389
Users baseDN	A limitation of the search scope of objects in the LDAP directory that is used in user search requests	—	ou=Peoples,dc=ad,dc=ranger-test
Groups baseDN	A limitation of the search scope of objects in the LDAP directory that is used in group search requests	—	ou=Groups,dc=ad,dc=ranger-test
Users filter	An LDAP filter that is used to search users. Should be specified according to the RFC 2254	(&(objectClass=person)(objectClass=inetOrgPerson))(cn=*))	(&(objectClass=person)(objectClass=organizationalPerson)(givenName=*)(sn=*)(sAMAccountName=*))
Groups filter	An LDAP filter that is used to search groups. Should be specified according to the RFC 2254	(&(objectClass=group)(objectClass=groupOfNames)(objectClass=groupOfUniqueNames))(cn=*))	(cn=*)
SA Login	A user name that is used for service requests to the LDAP server	—	cn=admin,dc=ad,dc=ranger-test
Password	A user password that is used for service requests to the LDAP server	—	A password of the `admin` user
Lowercase login	Defines whether to convert user names to lowercase	false	false
Lowercase group	Defines whether to convert group names to lowercase	false	false
Sync interval	A `cron` expression that defines how often synchronization of ADB users and groups with an LDAP server should be performed. The pg-ldap-sync utility, which comes with the ADB bundle, is used for synchronization	0 * * * *	0 * * * *

NOTE

Various LDAP implementations use different names for object types and identifiers. It is recommended to refine the settings format for a specific LDAP implementation from the LDAP server administrator.

5. Click ***Save***. Then apply the ***Reconfigure*** action to the ADB service.



Configure LDAP authentication for ADB via ADCM

Synchronize ADB and LDAP

If LDAP authentication is configured successfully, the following operations are performed in ADB automatically:

- **Update of the pg_hba.conf file**. The following entry about LDAP authentication is added to the *pg_hba.conf* file, which is located in the data directory of the coordinator host (*/data1/master/gpseg-1/* in the following example):

```
# BEGIN LDAP
host all <ldap_users 0.0.0.0/0 ldap ldapserver=<LDAP Host> ldapport=<LDAP Port> ldapbasedn="<Users baseDN>" ldapbinddn="<SA Login>" ldapbindpasswd="<Password>" ldapsearchattribute="<attribute>"
# END LDAP
```

  where:

  - `ldap_users` — a name of the ADB role, to which all LDAP users will be added.
  - `<LDAP Host>`, `<LDAP Port>`, `<Users baseDN>`, `<SA Login>`, `<Password>` — values of the eponymous parameters of the ADB service.
  - `<attribute>` — the LDAP attribute whose value will be used as a name of each role in ADB when synchronizing users. Possible values:
    - `sAMAccountName` — for MS AD.
    - `uid` — for FreeIPA.

- **Synchronization of ADB users and groups with LDAP**. Information about LDAP users and groups, which meet the selection criteria specified in the configuration step, is added to the ADB database. Synchronization is performed via the pg-ldap-sync utility. To ensure successful synchronization, you can run the following query against the `pg_roles` table:

```
SELECT rolname FROM pg_roles;
```

  As the SQL command output shows, the following roles are automatically created in ADB after successful LDAP synchronization:

  - `ldap_users` — a role into which all LDAP users are added (by running the `CREATE ROLE … LOGIN IN ROLE ldap_users …` command automatically).
  - `ldap_groups` — a role into which all LDAP groups are added (by running the `CREATE ROLE … NOLOGIN IN ROLE ldap_groups …` command automatically).
  - `ffedorov`, `ppetrov`, `ssemenov`, `zeptest` — all users received from the LDAP server and added to the `ldap_users` role.
  - `ADCM`, `ADH`, `Adccadmins`, `Analysts`, `Managers` — all groups received from the LDAP server and added to the `ldap_groups` role. The membership of users in these groups is set automatically by running `GRANT`.

```
   rolname
-------------
 gpadmin
 gpmon
 ldap_users
 ldap_groups
 ADCM
 ADH
 Adccadmins
 Analysts
 Managers
 ffedorov
 ppetrov
 ssemenov
 zeptest
(13 rows)
```

Synchronization details

- After initial configuration, ADB users are automatically synchronized with an LDAP server according to the schedule specified in the *Sync interval* parameter. There is no need to run the `CREATE ROLE` and `GRANT` commands manually.
- To synchronize ADB users with an LDAP server on demand (without waiting for the next auto launch), apply the ***Reconfigure*** action to the ADB service.
- After LDAP authentication is configured, only users registered on the LDAP server can connect to the ADB database. If you delete users on the LDAP side, they cannot further log in to ADB.
- If a user exists in ADB but not on the LDAP server side, synchronization does not affect this user. However, if a user with the same name exists both in ADB and on the LDAP server — the next time synchronization runs, the user data in ADB will be overwritten with the information received from LDAP.
- The `pg-ldap-sync` utility automates only the following DCL commands: `CREATE ROLE <ROLE>`, `DROP ROLE <ROLE>`, `GRANT <ROLE> TO <ROLE>`, and `REVOKE <ROLE> FROM <ROLE>`. The commands that define access privileges (e.g. `GRANT SELECT`, `GRANT EXECUTE`, `GRANT CONNECT`, `GRANT PRIVILEGES ON <OBJECT> TO <ROLE>`) should be run manually in ADB if necessary.

Check LDAP authentication

To check that LDAP authentication is properly configured in ADB, you can run `psql` to connect to ADB using the name of any LDAP user as the `-U` argument (`ffedorov` in the following example).

```
$ psql adb -h bds-mdw -U "ffedorov"
```

If LDAP authentication is configured successfully, you will be prompted to enter the user password. After entering the correct password (assigned on the LDAP server side), the user can access the database.

```
Password for user ffedorov:
psql (12.22)
Type "help" for help.

adb=>
```

LDAP authentication errors

- If a user with the specified name cannot be found among members of the `ldap_users` role in ADB, the following error occurs when you try to log in to ADB under that user:

```
psql: FATAL:  no pg_hba.conf entry for host "10.92.42.236", user "bds", database "adb", SSL off
```

- If a user with the specified name is a member of the `ldap_users` role in ADB, but the user name or password cannot be found in LDAP, the following error occurs when you try to log in to ADB under that user:

```
psql: FATAL:  LDAP authentication failed for user "bds"
```

In both cases, you should wait for automatic synchronization with an LDAP server or run it manually using the ***Reconfigure*** action of the ADB service.

Use PAM for LDAP authentication in AOB

Install and configure OpenLDAP server
- Set up FLDAP
- Install OpenLDAP packages
- Configure OpenLDAP server
- Create base groups
- Create a user
- Disable anonymous binding

Configure AOB coordinator

Check authentication

Pluggable authentication modules (PAM) is a mechanism that provides the ability to use multiple local authentication types or applications by means of the single login task API. PAM provides dynamic authentication for applications and services by the ability to edit rules, thus reducing the necessary systems, which provides flexibility and allows you to use different authentication methods without making changes to the code of the applications themselves.

This article describes how to use PAM for LDAP authentication in AOB.

Install and configure OpenLDAP server

The instructions below demonstrate how to install and configure an [OpenLDAP](https://www.openldap.org/) server on the **Ubuntu 16.04 64-bit(HVM) (x86_64)** instance with IP address **192.168.100.200** and the domain name **ldap.com**. Replace the IP address and domain with your LDAP server's. By default, it is the same as the domain name. You can create a new user, if necessary.

Set up FLDAP

1. Run the following command to set up the fully qualified domain name (FQDN) of your Ubuntu LDAP server:

```
sudo hostnamectl set-hostname ldap.com && exec bash && cat /etc/hostname
```

2. Open the /etc/hosts configuration file for editing:

```
sudo vi /etc/hosts
```

Add one line to the file in the **<IP> <FQDN> <hostname>** format:

```
192.168.100.200 ldap.com ldap
```

Save and close the file.

3. Run the command below to check the FQDN:

```
sudo hostname -f
```

Result:

```
ldap.com
```

4. Ping the hostname and ensure that you get response from the server IP address mapped to **hostname**:

```
ping ldap.com
```

Result:

```
PING ldap.com (192.168.100.200) 56(84) bytes of data.
64 bytes from ldap.com (192.168.100.200): icmp_seq=1 ttl=64 time=0.043 ms
64 bytes from ldap.com (192.168.100.200): icmp_seq=2 ttl=64 time=0.044 ms
64 bytes from ldap.com (192.168.100.200): icmp_seq=3 ttl=64 time=0.044 ms
^C
--- ldap.com ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 2028ms
rtt min/avg/max/mdev = 0.043/0.043/0.044/0.000 ms
```

Install OpenLDAP packages

1. Update all packages that are currently installed on your system:

```
sudo apt update
```

2. Install the OpenLDAP packages using the following command:

```
sudo apt install slapd ldap-utils
```

During the OpenLDAP server installation, you are asked to specify the **OMVSO** password for OpenLDAP admin (password). The same password is used in the next section.

Set up the administrator password for OpenLDAP

To find data during the LDAP database or LDAP directory, you can confirm the following dialog box:

Set up the Omit only database during purge?

Configure OpenLDAP server

1. Create a new domain.ldif file using the following command:

```
sudo vi domain.ldif
```

During the configuration process, you will see several dialog boxes with parameters. The following parameters are required:

- **Omit only database during purge?** — select the **No** option to avoid omitting the database during the purge of your LDAP directory.
- **Administrator password** — password of the **OMVSO** admin in the LDAP directory. Enter the password selected in step 2 of the [Install OpenLDAP packages](#) section. Then, confirm it in the next window.

Set up the administrator password for OpenLDAP

Set up the administrator password for OpenLDAP

Set up the Omit only database during purge?

2. Add the following text to the file:

```
dn: dc=ldap,dc=com
objectClass: top
objectClass: dcObject
objectClass: organization
o: ldap.com
dc: ldap

dn: cn=admin,dc=ldap,dc=com
objectClass: organizationalRole
cn: admin
description: LDAP Manager

dn: ou=people,dc=ldap,dc=com
objectClass: organizationalUnit
ou: people

dn: ou=groups,dc=ldap,dc=com
objectClass: organizationalUnit
ou: groups
```

Save and close the file.

3. Run the **slapadd** command to add groups from the previously created file to the LDAP directory:

```
sudo slapadd -v -l /etc/ldap/schema/domain.ldif -F /etc/ldap/slapd.d/
```

Result:

```
added: "dc=ldap,dc=com" (00000001)
added: "cn=admin,dc=ldap,dc=com" (00000002)
```

4. Run the **ldapsearch** command to check that new groups have been created:

```
sudo ldapsearch -H ldap:/// -x -b dc=ldap,dc=com
```

The command returns the list of groups:

```
# extended LDIF
#
# LDAPv3
# base <dc=ldap,dc=com> with scope subtree
# filter: (objectclass=*)
# requesting: ALL
#

# ldap.com
dn: dc=ldap,dc=com
objectClass: top
objectClass: dcObject
objectClass: organization
o: ldap.com
dc: ldap

# admin, ldap.com
dn: cn=admin,dc=ldap,dc=com
objectClass: organizationalRole
cn: admin
description: LDAP Manager

# people, ldap.com
dn: ou=people,dc=ldap,dc=com
objectClass: organizationalUnit
ou: people

# groups, ldap.com
dn: ou=groups,dc=ldap,dc=com
objectClass: organizationalUnit
ou: groups

# search result
search: 2
result: 0 Success

# numResponses: 4
# numEntries: 3
```

Create base groups

1. Create a new LDIF file using the command below:

```
sudo vi base.ldif
```

2. Add the text below to the file. **People** (for storing users) and **Groups** (for storing groups):

```
dn: ou=People,dc=ldap,dc=com
objectClass: organizationalUnit
ou: People

dn: ou=Groups,dc=ldap,dc=com
objectClass: organizationalUnit
ou: Groups
```

Save and close the file.

3. Run the **ldapadd** command to add groups from the previously created file to the LDAP directory:

```
sudo ldapadd -x -D cn=admin,dc=ldap,dc=com -W -f base.ldif
```

Enter the **admin** password to confirm the operation.

The command returns result:

```
adding new entry "ou=People,dc=ldap,dc=com"
adding new entry "ou=Groups,dc=ldap,dc=com"
```

4. Run the **ldapsearch** command to check that new groups have been created:

```
sudo ldapsearch -H ldap:/// -x -b dc=ldap,dc=com
```

The command returns the list of groups:

```
# extended LDIF
#
# LDAPv3
# base <dc=ldap,dc=com> with scope subtree
# filter: (objectclass=*)
# requesting: ALL
#

# ldap.com
dn: dc=ldap,dc=com
objectClass: top
objectClass: dcObject
objectClass: organization
o: ldap.com
dc: ldap

# admin, ldap.com
dn: cn=admin,dc=ldap,dc=com
objectClass: organizationalRole
cn: admin
description: LDAP Manager

# People, ldap.com
dn: ou=People,dc=ldap,dc=com
objectClass: organizationalUnit
ou: People

# Groups, ldap.com
dn: ou=Groups,dc=ldap,dc=com
objectClass: organizationalUnit
ou: Groups

# search result
search: 2
result: 0 Success

# numResponses: 5
# numEntries: 4
```

Create a user

1. Create the file using the command below. Note the following:

- In the **dn:** parameter, **ou=People** is the value of the **People** parameter of the previous group.
- You can substitute the **People** value with your own value if you have set it in the previous group.

```
dn: uid=alice,ou=People,dc=ldap,dc=com
uidNumber: 10000
gidNumber: 10000
cn: alice
sn: Doe
objectClass: inetOrgPerson
objectClass: posixAccount
objectClass: shadowAccount
userPassword: changeme
loginShell: /bin/bash
homeDirectory: /home/alice
shadowLastChange: 0
shadowMax: 0
shadowWarning: 0
```

Save and close the file.

2. Run the **ldapadd** command to add a user from the LDAP directory:

```
sudo ldapadd -x -D cn=admin,dc=ldap,dc=com -W -f user.ldif
```

Enter the **admin** password to confirm the operation.

The command returns result:

```
adding new entry "uid=alice,ou=People,dc=ldap,dc=com"
```

3. Check that the user was added to the LDAP directory:

```
sudo ldapsearch -H ldap:/// -x -b dc=ldap,dc=com '(uid=alice)' cn uidNumber gidNumber
```

Result:

```
# extended LDIF
#
# LDAPv3
# base <dc=ldap,dc=com> with scope subtree
# filter: (uid=alice)
# requesting: cn uidNumber gidNumber
#

# alice, People, ldap.com
dn: uid=alice,ou=People,dc=ldap,dc=com
cn: alice
uidNumber: 10000
gidNumber: 10000

# search result
search: 2
result: 0 Success

# numResponses: 2
# numEntries: 1
```

Disable anonymous binding

Optional

If you disable anonymous binding in LDAP as follows, it will be necessary to fill in the **binddn** and **bindpw** options in the PAM configuration file also mentioned later in the [Configure AOB coordinator](#) section.

If you want to disable anonymous binding on an LDAP server, perform the following:

1. Create a new LDIF file:

```
sudo vi ldap_disable_bind_anon.ldif
```

Add the following text to the file:

```
dn: cn=config
changetype: modify
add: olcDisallows
olcDisallows: bind_anon

dn: cn=config
changetype: modify
add: olcRequires
olcRequires: authc

dn: olcDatabase={-1}frontend,cn=config
changetype: modify
add: olcRequires
olcRequires: authc
```

Save and close the file.

2. Run the **ldapmodify** command to apply changes:

```
sudo ldapmodify -Y EXTERNAL -H ldapi:/// -f ldap_disable_bind_anon.ldif
```

Result:

```
SASL/EXTERNAL authentication started
SASL username: gidNumber=0+uidNumber=0,cn=peercred,cn=external,cn=auth
SASL SSF: 0
modifying entry "cn=config"
modifying entry "cn=config"
modifying entry "olcDatabase={-1}frontend,cn=config"
```

Configure AOB coordinator

Run the following commands on the AOB coordinator host:

1. Update all packages that are currently installed on your system:

```
sudo apt update
```

2. Install the [libpam-ldapd](https://packages.ubuntu.com/xenial/libpam-ldapd) package:

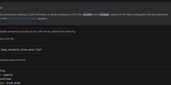
```
sudo apt install libpam-ldapd
```

During the configuration process, you will see several dialog boxes with parameters. The following parameters are required:

- **LDAP server search base** — base DN for LDAP searches. For example, **ldap://192.168.100.200/dc=ldap,dc=com**.

Set up the LDAP server search base

- **LDAP server bind DN** — base DN for LDAP search. For example, **dn:cn=admin,dc=ldap,dc=com**.



Set up the LDAP server bind DN

- **LDAP password** — password of the **OMVSO** admin in the LDAP directory. Enter the password selected in step 2 of the [Install OpenLDAP packages](#) section. Then, confirm it in the next window.

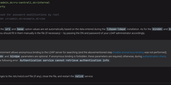
Set up the LDAP password

Set up the LDAP password

- **Name services to configure** — select the **passwd** and **group** options.

Set up the name services to configure

- **LDAP configuration is secure** — select the **No** option.

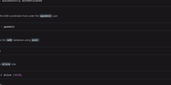


Set up the LDAP configuration is secure

- **Make local root database even if unreachable** — select the **No** option.

Set up the Make local root database even if unreachable

- **Make root user password behave like any other** — select the **No** option.



Set up the Make root user password behave like any other

- **Root login account** — select the **No** option.

Set up the Root login account

- **Root bind password** — select the **No** option.

Set up the Root bind password

3. Open the /etc/pam.d/common-password configuration file for editing:

```
sudo vi /etc/pam.d/common-password
```

Add the following text to the file:

```
password [success=2 default=ignore] pam_unix.so obscure sha512
password [success=1 user_unknown=ignore default=die] pam_ldap.so try_first_pass
password requisite pam_deny.so
password required pam_permit.so
```

Save and close the file.

4. Open the /etc/pam.d/common-session configuration file for editing:

```
sudo vi /etc/pam.d/common-session
```

Add the following text to the file:

```
session [default=1] pam_permit.so
session required pam_unix.so
session optional pam_ldap.so
```

Save and close the file.

5. Open the /etc/nsswitch.conf configuration file for editing:

```
sudo vi /etc/nsswitch.conf
```

Add the following text to the file:

```
passwd: files ldap
group: files ldap
shadow: files ldap
```

Save and close the file.

6. Open the /etc/ldap.conf configuration file for editing:

```
sudo vi /etc/ldap.conf
```

Add the following text to the file:

```
base dc=ldap,dc=com
uri ldap://192.168.100.200
ldap_version 3
binddn cn=admin,dc=ldap,dc=com
bindpw changeme
pam_password md5
```

Save and close the file.

Check authentication

To check PAM authentication, run the following commands on the AOB coordinator host:

1. Optionally install the **pamtester** utility (a service that uses PAM to test PAM services):

```
sudo apt install pamtester
```

2. Optionally run the **pamtester** utility passing a service and the [testing user](#) (**alice**) to check PAM authentication:

```
pamtester passwordsvc alice authenticate
```

After running the utility, enter the [password](#) set in the [Create a user](#) section. The successful authentication result is shown below:

```
pamtester: successfully authenticated
```

3. Log in to the AOB coordinator host under the [testing user](#):

```
sudo su - ubuntu
```

4. Connect to the **AOB** database using **psql**:

```
psql AOB
```

5. Create the **ACCESS** role:

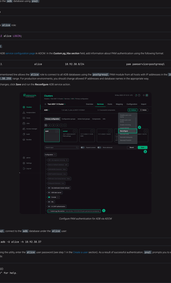
```
CREATE ROLE access;
```

Grant the **Execute_Obj_Methods** role to the **ACCESS** role. Substitute **Execute_Obj_Methods** with your own role if necessary:

```
GRANT "Execute_Obj_Methods" TO access;
```

6. Create the **alice** user with the **ACCESS** role and password (see step 1 of the [Create a user](#) section). As a result of successful authentication, **psql** will grant you an interactive shell prompt:

```
CREATE USER alice
WITH PASSWORD 'changeme'
IN ROLE access;
```



Configure PAM authentication for LDAP on AOB#

7. Install **psql**, connect to the **AOB** database under the **alice** user:

```
psql -U alice -h localhost -d AOB
```

8. After running the utility, enter the **alice** user password (see step 1 of the [Create a user](#) section). As a result of successful authentication, **psql** will grant you an interactive shell prompt:

```
psql (10.10)
Type "help" for help.
AOB=>
```

Use MIT Kerberos KDC in AOB

Contents

Step 1. Install and configure MIT Kerberos KDC

Step 2. Create a test principals for AOB in MIT Kerberos KDC

Step 3. Configure Kerberos authentication for client applications

Step 4. Use Kerberos authentication in AOB roles

Step 5. Configure Kerberos authentication for other applications

Client's JDBC connection connections

Step 1. Install and configure MIT Kerberos KDC

Skip if you already have an Kerberos service available for use in AOB. [Proceed to step 2](#)

Here we will choose to install and configure MIT Kerberos KDC from the source code. Download the latest krb5-1.21.3.tar.gz file. Transfer it to the `/tmp` directory on the AOB server.

Log in to the AOB server as root and decompress the source code:

```
# cd /tmp
# tar zxvf krb5-1.21.3.tar.gz
```

Use the following instructions to configure the source code for `/usr` or `/usr/local`:

```
# cd krb5-1.21.3/src
# ./configure --prefix=/usr --localstatedir=/var/kerberos --sysconfdir=/etc/kerberos
```

Build and install the software:

```
# make
# make install
```

Create the configuration file `/etc/kerberos/krb5.conf` with the following contents:

```
[libdefaults]
    default_realm = EXAMPLE.COM
    dns_lookup_realm = false
    dns_lookup_kdc = false
    ticket_lifetime = 24h
    renew_lifetime = 7d
    forwardable = true
    rdns = false
    default_tkt_enctypes = aes256-cts-hmac-sha1-96 aes128-cts-hmac-sha1-96
    default_tgs_enctypes = aes256-cts-hmac-sha1-96 aes128-cts-hmac-sha1-96
    permitted_enctypes = aes256-cts-hmac-sha1-96 aes128-cts-hmac-sha1-96

[realms]
    EXAMPLE.COM = {
        kdc = kerberos.example.com
        admin_server = kerberos.example.com
    }

[domain_realm]
    .example.com = EXAMPLE.COM
    example.com = EXAMPLE.COM

[logging]
    default = FILE:/var/log/krb5libs.log
    kdc = FILE:/var/log/krb5kdc.log
    admin_server = FILE:/var/log/kadmind.log
```

Create the KDC profile file `/etc/kerberos/kdc.conf` with the following contents:

```
[kdcdefaults]
    kdc_ports = 750,88

[realms]
    EXAMPLE.COM = {
        acl_file = /etc/kerberos/kadm5.acl
        dict_file = /usr/share/dict/words
        admin_keytab = /etc/kerberos/kadm5.keytab
        supported_enctypes = aes256-cts-hmac-sha1-96:normal aes128-cts-hmac-sha1-96:normal
    }
```

Create the ACL profile file `/etc/kerberos/kadm5.acl` with the following contents. This example is used to only the root user on any host can be managed by the kadmin/admin service. See the [kadm5.acl](#) manual page for more information.

```
*/admin@EXAMPLE.COM    *
```

Create the KDC database and set the master password:

```
# /usr/sbin/kdb5_util create -s
```

```
Loading random data
Initializing database '/var/kerberos/krb5kdc/principal' for realm 'EXAMPLE.COM',
master key name 'K/M@EXAMPLE.COM'
You will be prompted for the database Master Password.
It is important that you NOT FORGET this password.
Enter KDC database master key:
Re-enter KDC database master key to verify:
```

Create `/etc/kerberos/stash` and create an administrative principal in the database. Try to also use the [kadmin.local](#) tool.

```
# /usr/sbin/kadmin.local -q "addprinc admin/admin"
```

```
Authenticating as principal root/admin@EXAMPLE.COM with password.
WARNING: no policy specified for admin/admin@EXAMPLE.COM; defaulting to no policy
Enter password for principal "admin/admin@EXAMPLE.COM":
Re-enter password for principal "admin/admin@EXAMPLE.COM":
Principal "admin/admin@EXAMPLE.COM" created.
```

To grant the appropriate permissions to the administrative user add the [/etc/kerberos/kadm5.acl](#) file:

```
# echo 'admin/admin *' > /etc/kerberos/kadm5.acl
```

Start the KDC daemon:

```
# /usr/sbin/krb5kdc
```

Start the kadmin daemon. Use the `-r` option to specify the default realm if you have multiple realms in the configuration file:

```
# /usr/sbin/kadmind -r EXAMPLE.COM
```

Add the KDC and kadmin daemons to the system startup:

```
# echo '/usr/sbin/krb5kdc' >> /etc/rc.d/rc.local
# echo '/usr/sbin/kadmind -r EXAMPLE.COM' >> /etc/rc.d/rc.local
```

Test the KDC and kadmin daemons:

```
# kinit admin/admin
```

```
Password for admin/admin@EXAMPLE.COM:
```

```
# klist
```

```
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: admin/admin@EXAMPLE.COM

Valid starting     Expires            Service principal
05/21/2024 15:54:31  05/22/2024 15:54:31  krbtgt/EXAMPLE.COM@EXAMPLE.COM
```

```
# kadmin
```

```
Authenticating as principal admin/admin@EXAMPLE.COM with password.
Password for admin/admin@EXAMPLE.COM:
kadmin:  getprincs
K/M@EXAMPLE.COM
admin/admin@EXAMPLE.COM
kadmin/admin@EXAMPLE.COM
kadmin/changepw@EXAMPLE.COM
kadmin/kerberos.example.com@EXAMPLE.COM
kiprop/kerberos.example.com@EXAMPLE.COM
krbtgt/EXAMPLE.COM@EXAMPLE.COM
kadmin:  quit
```

Configure the system clock synchronization.

Configure the firewall to allow access to the KDC and kadmin services.

Step 2. Create principals for AOB in MIT Kerberos KDC

A principal is the service with which Kerberos can assign tickets and a keytab is a repository that stores one or more principals and their encrypted keys. Create a principal for the AOB server and a keytab file to store the principal's key. Use the [kadmin](#) tool:

```
# kadmin
```

```
Authenticating as principal admin/admin@EXAMPLE.COM with password.
Password for admin/admin@EXAMPLE.COM:
```

Add the principal `aob/aob.example.com@EXAMPLE.COM`:

```
kadmin:  addprinc -randkey aob/aob.example.com@EXAMPLE.COM
```

```
WARNING: no policy specified for aob/aob.example.com@EXAMPLE.COM; defaulting to no policy
Principal "aob/aob.example.com@EXAMPLE.COM" created.
```

Create the keytab file `/etc/kerberos/aob.keytab` and add the principal `aob/aob.example.com@EXAMPLE.COM` to it:

```
kadmin:  ktadd -k /etc/kerberos/aob.keytab aob/aob.example.com@EXAMPLE.COM
```

```
Entry for principal aob/aob.example.com@EXAMPLE.COM with kvno 2, encryption type aes256-cts-hmac-sha1-96 added to keytab WRFILE:/etc/kerberos/aob.keytab.
Entry for principal aob/aob.example.com@EXAMPLE.COM with kvno 2, encryption type aes128-cts-hmac-sha1-96 added to keytab WRFILE:/etc/kerberos/aob.keytab.
```

Exit the kadmin tool:

```
kadmin:  quit
```

Test if the principal can obtain the ticket-granting ticket (TGT) from the KDC:

```
# kinit -k -t /etc/kerberos/aob.keytab aob/aob.example.com@EXAMPLE.COM
```

```
# klist
```

```
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: aob/aob.example.com@EXAMPLE.COM

Valid starting     Expires            Service principal
05/21/2024 15:57:31  05/22/2024 15:57:31  krbtgt/EXAMPLE.COM@EXAMPLE.COM
```

Step 3. Configure Kerberos authentication for client applications

Configure the client machine to use the Kerberos service. Install the Kerberos client software. Copy the `/etc/kerberos/krb5.conf` file from the KDC server to the client machine.

Create a test principal for the client machine and add it to the keytab file `/etc/kerberos/client.keytab`:

```
# kadmin
```

```
Authenticating as principal admin/admin@EXAMPLE.COM with password.
Password for admin/admin@EXAMPLE.COM:
```

```
kadmin:  addprinc -randkey host/client.example.com@EXAMPLE.COM
```

```
WARNING: no policy specified for host/client.example.com@EXAMPLE.COM; defaulting to no policy
Principal "host/client.example.com@EXAMPLE.COM" created.
```

```
kadmin:  ktadd -k /etc/kerberos/client.keytab host/client.example.com@EXAMPLE.COM
```

```
Entry for principal host/client.example.com@EXAMPLE.COM with kvno 2, encryption type aes256-cts-hmac-sha1-96 added to keytab WRFILE:/etc/kerberos/client.keytab.
Entry for principal host/client.example.com@EXAMPLE.COM with kvno 2, encryption type aes128-cts-hmac-sha1-96 added to keytab WRFILE:/etc/kerberos/client.keytab.
```

```
kadmin:  quit
```

Test if the client can obtain the TGT from the KDC:

```
# kinit -k -t /etc/kerberos/client.keytab host/client.example.com@EXAMPLE.COM
```

```
# klist
```

```
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: host/client.example.com@EXAMPLE.COM

Valid starting     Expires            Service principal
05/21/2024 15:59:31  05/22/2024 15:59:31  krbtgt/EXAMPLE.COM@EXAMPLE.COM
```

Accounts in ADB

Daria Barysheva

Contents

To Table of Contents

Linux users

Arenadata DB roles

Accounts used in the ADB Control databases

ADB Control UI users

ADBM API user

ADCM user

LDAP accounts

- ADB
- ADB Control

This article lists all accounts that are used in Arenadata DB.

Linux users

The following accounts are created in an operating system during ADB installation (*/etc/passwd*).

Account	Description	Default password
adcm	The user that is used by ADCM to deploy clusters	Not set
gpadmin	The Linux user for ADB that is needed to start/stop a cluster and run all console utilities. Also, it has access to all cluster databases as a superuser (with the `trust` method in *pg_hba.conf*). You can change this username via the ***System user name*** setting in configuration parameters of the ADB service	Not set
pxf	The user for PXF. Assigned `nologin` in */etc/passwd*	Not set

Arenadata DB roles

The following accounts are created in the Arenadata DB database during ADB installation (via the `CREATE ROLE` command).

Account	Description	Default password	How to change a password
gpadmin	The ADB cluster administrator. This role has access to all cluster databases as a superuser	Not set	Via the `psql` utility: `ALTER ROLE gpadmin WITH ENCRYPTED PASSWORD '<new_password>';` There is no ability to set/change a password via ADCM
adcc	The role that is used by ADB Control for connecting to ADB. Such access is required to obtain information about the cluster topology and to cancel requests initiated by users. The username can be changed on the ADB Control configuration page during the primary ADB Control installation. Not possible to change after. For more information, see Configuration parameters (***ADB Control → UI component parameters → ADB user name***)	Not set by default. Cannot be set during ADB installation. A password is stored in `pg_shadow`	1. Run the following command via the `psql` utility: `ALTER ROLE adcc WITH ENCRYPTED PASSWORD '<new_password>';` 2. Change the password on the ***Configuration → Clusters*** tab in the ADB Control UI. For more information, see Edit a cluster connection. There is no ability to set/change a password via ADCM

Accounts used in the ADB Control databases

The following accounts are created in the ADB Control databases (containerized or external) during ADB Control installation.

Account	Description	Default password	How to change a password
postgres	The role name in the PostgreSQL database, which is used in ADB Control to store information on data queries (see Query DB). The username can be changed on the ADB Control configuration page during ADB Control installation. For more information, see Configuration parameters (***ADB Control → Database parameters → Username*** or ***ADB Control → External database parameters → Username*** for external PostgreSQL).	The default value is `123`. Can be set on the ADB Control configuration page during ADB Control installation. For more information, see Configuration parameters (***ADB Control → Database parameters → Password*** or ***ADB Control → External database parameters → Password*** for external PostgreSQL)	For external PostgreSQL, you can change a password via ADCM anytime. For containerized PostgreSQL, you can set a password only during the primary ADB Control installation
default	The account name in the ClickHouse database, which is used in ADB Control to store information on metrics (see Metrics DB). The username can be changed on the ADB Control configuration page during ADB Control installation. For more information, see Configuration parameters (***ADB Control → ADQM database parameters → Username*** or ***ADB Control → External ADQM parameters → Username*** for external ClickHouse)	Not set by default. Can be set on the ADB Control configuration page during ADB Control installation. For more information, see Configuration parameters (***ADB Control → ADQM database parameters → Password*** or ***ADB Control → External ADQM parameters → Password*** for external ClickHouse). If set, a password is stored in the ADCM vault and in ClickHouse	For external ClickHouse, you can change a password via ADCM anytime. For containerized ClickHouse, you can set a password only during the primary ADB Control installation

ADB Control UI users

The following users are created during ADB Control installation.

Account	Description	Default password	How to change a password

admin	The ADB Control owner, which is used to work with ADB Control UI	The default value is `1234`.
		When you first log in to ADB Control, you should change a password. For more information, see Connect to ADB Control.
		A password is stored in the `adcc.user` table of the PostgreSQL database (containerized or external):
		`$ psql -d adcc`
		`SELECT * FROM adcc.user;`
			You can change a password on the ***Users → Management*** tab in the ADB Control UI. For more information, see Edit a user

adcm	The service API user (hidden administrator of the ADB Control UI)	Can be set on the ADB Control configuration page during ADB Control installation. For more information, see Configuration parameters (***ADB Control → UI component parameters → Service password***). If not set, a secret password is generated. For backward compatibility, it is the same across all clusters. A password is stored in encrypted form in the `adcc_database_1` container: `SELECT password FROM adcc.system_user WHERE username = 'adcm';`	Password can be reset on the ADB Control configuration page (***ADB Control → UI component parameters → Service password***)
adbm	The service API user (hidden administrator of the ADB Control UI) for collecting information about storage and cluster modifications that is displayed on the ***Audit*** page	Can be set on the ADBM configuration page. For more information, see Configuration parameters (***ADBM → Password for adbm system-user***). A password is stored in encrypted form in the `adcc_database_1` container: `SELECT password FROM adcc.system_user WHERE username = 'adbm';`	Password can be changed on the ADBM configuration page (***ADBM → Password for adbm system-user***).

ADBM API user

The following user is created during ADBM installation.

Account	Description	Default password	How to change a password

adcc	The user that is used for authentication in the ADBM CLI API	Stored as plaintext in the */opt/adbm/auth.properties* file. The default value is `1234`.
		`user.adcc = 1234`
		File permissions:
		`-rw-r--r-- 1 root root`
			Update the */opt/adbm/auth.properties* file. The ADBM restart is required

ADCM user

The following user is created during ADCM installation.

Account	Description	Default password	How to change a password
admin	ADCM admin	admin	After ADCM installation is complete, you can change a user password in the ADCM web UI. For more information, see Check the ADCM web-interface

LDAP accounts

When configuring LDAP authentication, you need to enter and store LDAP admin accounts. Passwords are stored as plaintext in specific files that should be secured with OS file permissions.

ADB

LDAP authentication in ADB is configured according to the LDAP authentication in ADB article. To specify the LDAP admin account and its password, fill in the ***SA Login*** and ***Password*** fields on the ADB configuration page.

LDAP credentials are stored in the following file on the ADB coordinator host: *$COORDINATOR_DATA_DIRECTORY/pg_hba.conf*.

File permissions:

```
-rw-r----- 1 gpadmin gpadmin
```

Synchronization of ADB users and groups with LDAP is performed automatically via the pg-ldap-sync utility. For more information, see Synchronize ADB and LDAP.

IMPORTANT

After syncing with the LDAP server, two ADB local roles are still required since they cannot be replaced with LDAP users (see Arenadata DB roles):

- `gpadmin`
- `gpmon`

All other users (including superusers) can be controlled via the LDAP server.

ADB Control

LDAP authentication in ADB Control is configured according to the LDAP authentication article. To specify the LDAP admin account and its password, fill in the ***Login*** and ***Password*** fields on the ADB Control configuration page.

LDAP credentials are stored in the following files on the ADB Control host:

- */opt/adcc/docker-compose.yaml*. File permissions:

```
-rw------- 1 root root
```

- */opt/adcc/adcc-ui-server-application.yml*. File permissions:

```
-rw-r--r--  1 root root
```

If LDAP authentication is configured, you need to map user groups of the selected LDAP server to roles in ADB Control. You can manage such mappings on the ***Users → LDAP group mapping*** tab in the ADB Control web interface. For more information, see Configure role mappings with LDAP groups.

IMPORTANT

After you assign the `Administrator` or `Owner` role to specific LDAP users and delete or block the default local user `admin` (see ADB Control UI users) in ADB Control, all authentication can be controlled via the LDAP server.

Cluster actions

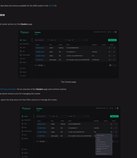
Contents

- Overview
- Activate standby
- Activate standby postprocessing
- Init Standby Master
- Move Host Segment
- Expand
- Prepare
- Run the action
- Start
- Reinstall vistacrecher
- Reconfigure Yauti integration
- Reconfigure parameter archiving
- Check
- Start
- Stop
- Upgrade
- Uninstall

The cluster actions are available in the portal from the cluster's [Actions] tab.

Overview

You can find cluster actions in the **Overview** tab:



Each action is available under a button.

Many [Greenplum clusters](#) do not contain a **Standby** host (see [Standby Master Segment](#)).

The **Standby** cluster node is required for the following actions:

- [Init Standby Master](#)
- [Activate standby](#)

Each action is available under a button.

- [Activate standby](#) — to activate a node with a standby role (if available) and [switch the roles](#).
- [Init Standby Master](#) — to create a standby node for the master node.

Each of the actions is available after the cluster runs [Greenplum](#) in the current UAR cluster status:

Action	Available	Available actions
Activate standby	Available after the cluster runs [Greenplum](#) in the current UAR cluster status:	Activate standby
Init Standby Master	The action is available for the cluster with the [Greenplum](#) role in the current UAR cluster status:	Expand Prepare Run the action Start Reinstall vistacrecher Reconfigure Yauti integration Reconfigure parameter archiving Check Start Stop Upgrade Uninstall

Activate standby

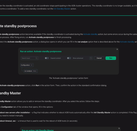
The **Activate standby** action is available for clusters in one of these roles in the current installation:

- [Greenplum](#)
- [Greenplum with standby](#)

The action is available for clusters whose hosts in the current installation have the [Greenplum master](#) role and the [Greenplum standby master](#) role. The action is available for clusters whose hosts in the current installation have the [Greenplum master](#) role and the [Greenplum standby master](#) role in the [Greenplum with standby](#) cluster.

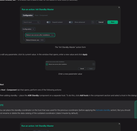
With the action, the [Greenplum standby master](#) is activated, which will work as the new master node.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.



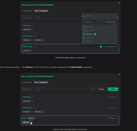
The Activate standby window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.



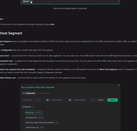
The Activate standby window with the filled-in data

The [Activate standby](#) action will be in the cluster's list. The action will start running.



The Activate standby action is running

When the action is complete, the **[ACTIVATE]** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons. The standby node will become a master node, and the master node will become a standby node. The [Greenplum with standby](#) cluster will change its role to [Greenplum](#).



The Activate standby action is complete

Postprocessing

- Expand [Greenplum with standby](#) cluster nodes by adding the **Activate standby** action to the [Expand](#) action.
- Add the [Init Standby Master](#) action to the [Greenplum with standby](#) cluster.
- Move Segment to the standby node — to move the data to the new master node. See [Move Host Segment](#).

Available actions after the action:

- [Init Standby Master](#) — to create a standby node for the master node.
- [Move Host Segment](#) — to move the data to the new master node. See [Move Host Segment](#).
- [Expand](#) — to add new nodes to the cluster. See [Expand](#).

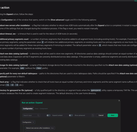
Activate standby postprocess

The **Activate standby postprocess** action is available for clusters in the [Greenplum with standby](#) role in the current installation.

The action is available for clusters whose hosts in the current installation have the [Greenplum master](#) role and the [Greenplum standby master](#) role in the [Greenplum with standby](#) cluster.

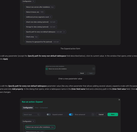
With the action, the [Greenplum standby master](#) is activated, which will work as the new master node.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.



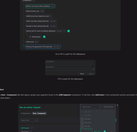
The Activate standby postprocess window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.



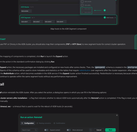
The Activate standby postprocess window with the filled-in data

The [Activate standby postprocess](#) action will be in the cluster's list. The action will start running.



The Activate standby postprocess action is running

When the action is complete, the **[ACTIVATE]** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons. The standby node will become a master node, and the master node will become a standby node. The [Greenplum with standby](#) cluster will change its role to [Greenplum](#).



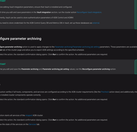
The Activate standby postprocess action is complete

Init Standby Master

Use the **Init Standby Master** action to add a standby node for the master node.

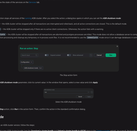
The action is available for clusters in the [Greenplum](#) role in the current installation.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Select Host** — a drop-down list for selecting the host for the standby node. The **Select Host** field is required.



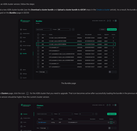
The Init Standby Master window

1. Click the **Select Host** field.
2. In the list, choose a host for the standby node.
3. Enter the name in the **Name** field.
4. Enter a description in the **Description** field if necessary.



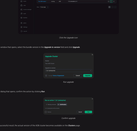
The Init Standby Master window with the filled-in data

5. Click the **Run action** button. The [Init Standby Master](#) action will be in the cluster's list. The action will start running.



The Init Standby Master action is running

When the action is complete, the **Init Standby Master** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons. The [Greenplum](#) cluster will change its role to [Greenplum with standby](#).



The Init Standby Master action is complete

Move Host Segment

Use the **Move Host Segment** action to move the data to the new master node.

The action is available for clusters in the [Greenplum with standby](#) role in the current installation.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Select Host** — a drop-down list for selecting the host for the standby node. The **Select Host** field is required.
- **Disconnect users** — a parameter that is responsible for the behavior of the system when the action is run. If the parameter is enabled, the system will disconnect all users from the database when the action is run. If the parameter is disabled, the system will not disconnect users from the database when the action is run. The parameter is disabled by default.
- **Maintenance mode** — a parameter that is responsible for the maintenance mode when the action is run. If the parameter is enabled, the system will enable the maintenance mode when the action is run. If the parameter is disabled, the system will not enable the maintenance mode when the action is run. The parameter is disabled by default.
- **Select Segment** — a drop-down list for selecting the segment for the standby node. The **Select Segment** field is required.

The Move Segment window

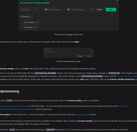
To start the operation, enter the name in the **Name** field, enter a description in the **Description** field if necessary, select the host in the **Select Host** field, select the segment in the **Select Segment** field, and click the **Run action** button.

The Move Segment window with the filled-in data

The [Move Segment](#) action will be in the cluster's list. The action will start running.

The Move Segment action is running

When the action is complete, the **Move Segment** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.



The Move Segment action is complete

Expand

The [Expand](#) action will add new segment hosts to the [UAR](#) cluster.

Prepare

Before running the action:

- Add the segment hosts in the **Hosts** tab. [UAR](#) will install on the added hosts.
- Add segment hosts using the [Add Greenplum segment hosts](#) action in the **Cluster operations** tab. Parameters will be set automatically according to the [Greenplum](#) cluster settings.

Prepare the cluster using the action:

Start the cluster in the Prepare mode

The Prepare window

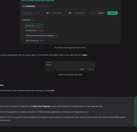
To start the action, enter the name in the **Name** field, enter a description in the **Description** field if necessary, and click the **Run action** button.

The Prepare window with the filled-in data

The [Prepare](#) action will be in the cluster's list. The action will start running.

The Prepare action is running

When the action is complete, the **Prepare** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

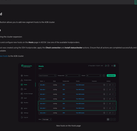


The Prepare action is complete

Run the action

Run the [Expand](#) action:

- In the **Configuration** tab, find the action, select the **Use advanced** type and specify the following options:
  - **Segment hosts** — a list of segment hosts for the cluster. The **Segment hosts** field is required. Select the [Segment](#) role in the drop-down list.
  - **Segment data directory** — a list of directories for the segment data. The **Segment data directory** field is required.
  - **Segment mirror directory** — a list of directories for the segment mirror. The **Segment mirror directory** field is required.
  - **Segment port range** — a range of ports for the segment. The **Segment port range** field is required.
  - **Segment mirror port range** — a range of ports for the segment mirror. The **Segment mirror port range** field is required.
  - **Disconnect users** — a parameter that is responsible for the behavior of the system when the action is run. If the parameter is enabled, the system will disconnect all users from the database when the action is run. If the parameter is disabled, the system will not disconnect users from the database when the action is run. The parameter is disabled by default.
  - **Maintenance mode** — a parameter that is responsible for the maintenance mode when the action is run. If the parameter is enabled, the system will enable the maintenance mode when the action is run. If the parameter is disabled, the system will not enable the maintenance mode when the action is run. The parameter is disabled by default.
  - **Use gpexpand for the operation** — the gpexpand utility is responsible for the operation of the action. If the parameter is enabled, the system will use the gpexpand utility when the action is run. If the parameter is disabled, the system will not use the gpexpand utility when the action is run. The parameter is disabled by default.



The Expand window

- In the **Name** field, enter the name of the action.
- In the **Description** field, enter a description of the action if necessary.
- Click the **Run action** button. The [Expand](#) action will be in the cluster's list. The action will start running.

The Expand action is running

When the action is complete, the **Expand** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

The Expand action is complete

Start

Use the **Start** action to start the cluster.

The action is available for clusters in the [Greenplum](#) role in the current installation.

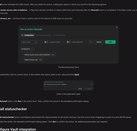
- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Start window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Start window with the filled-in data

The [Start](#) action will be in the cluster's list. The action will start running.



The Start action is running

When the action is complete, the **Start** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

The Start action is complete

Reinstall vistacrecher

The **Reinstall vistacrecher** action is available for clusters in the [Greenplum](#) role in the current installation.

The action is available for clusters whose hosts in the current installation have the [Greenplum master](#) role and the [Greenplum standby master](#) role in the [Greenplum with standby](#) cluster.

With the action, the [Greenplum standby master](#) is activated, which will work as the new master node.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Reinstall vistacrecher window

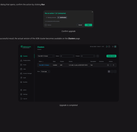
To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Reinstall vistacrecher window with the filled-in data

The [Reinstall vistacrecher](#) action will be in the cluster's list. The action will start running.

The Reinstall vistacrecher action is running

When the action is complete, the **Reinstall vistacrecher** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.



The Reinstall vistacrecher action is complete

Reconfigure Yauti integration

The **Reconfigure Yauti integration** action is available for clusters in the [UAR](#) cluster role in the current installation.

The action is available for clusters whose hosts in the current installation have the [Greenplum master](#) role and the [Greenplum standby master](#) role in the [Greenplum with standby](#) cluster.

With the action, the [Greenplum standby master](#) is activated, which will work as the new master node.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Reconfigure Yauti integration window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Reconfigure Yauti integration window with the filled-in data

The [Reconfigure Yauti integration](#) action will be in the cluster's list. The action will start running.

The Reconfigure Yauti integration action is running

When the action is complete, the **Reconfigure Yauti integration** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

The Reconfigure Yauti integration action is complete

Reconfigure parameter archiving

The **Reconfigure parameter archiving** action is available for clusters in the [Greenplum](#) role in the current installation.

The action is available for clusters whose hosts in the current installation have the [Greenplum master](#) role and the [Greenplum standby master](#) role in the [Greenplum with standby](#) cluster.

With the action, the [Greenplum standby master](#) is activated, which will work as the new master node.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Reconfigure parameter archiving window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Reconfigure parameter archiving window with the filled-in data

The [Reconfigure parameter archiving](#) action will be in the cluster's list. The action will start running.

The Reconfigure parameter archiving action is running

When the action is complete, the **Reconfigure parameter archiving** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

The Reconfigure parameter archiving action is complete

Check

The **Check** action checks the [Greenplum](#) cluster, [Greenplum standby](#) and [Greenplum segment](#) hosts for [UAR](#) and [Greenplum](#) errors.

The action is available for clusters in the [Greenplum](#) role in the current installation.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Check window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Check window with the filled-in data

The [Check](#) action will be in the cluster's list. The action will start running.

The Check action is running

When the action is complete, the **Check** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

The Check action is complete

Start

The **Start** action starts the cluster. [Greenplum](#), [Greenplum standby](#) and [Greenplum segment](#) hosts for [UAR](#) and [Greenplum](#) errors.

The action is available for clusters in the [Greenplum](#) role in the current installation.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Start window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Start window with the filled-in data

The [Start](#) action will be in the cluster's list. The action will start running.

The Start action is running

When the action is complete, the **Start** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

The Start action is complete

Stop

The **Stop** action stops the cluster. [Greenplum](#), [Greenplum standby](#) and [Greenplum segment](#) hosts for [UAR](#) and [Greenplum](#) errors.

The action is available for clusters in the [Greenplum](#) role in the current installation.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Stop window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Stop window with the filled-in data

The [Stop](#) action will be in the cluster's list. The action will start running.

The Stop action is running

When the action is complete, the **Stop** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

The Stop action is complete

Upgrade

The **Upgrade** action upgrades the [Greenplum](#), [Greenplum standby](#), and [Greenplum segment](#) hosts for [UAR](#) and [Greenplum](#) errors. The action is available for clusters in the [Greenplum](#) role in the current installation.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Distribution** — a drop-down list for selecting the distribution for the upgrade. The **Distribution** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Upgrade window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Upgrade window with the filled-in data

The [Upgrade](#) action will be in the cluster's list. The action will start running.

The Upgrade action is running

When the action is complete, the **Upgrade** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

The Upgrade action is complete

Uninstall

The **Uninstall** action uninstalls the [Greenplum](#) cluster.

The action is available for clusters in the [Greenplum](#) role in the current installation.

- **Name and Description** — fields for the name and description of the action. The fields are filled in automatically, but can be edited. The **Name** field is required.
- **Run action** — the button for starting the action. **[ACTIVATE]** becomes available when the **Name** field is filled in. The **Description** field is optional.

The Uninstall window

To start the action, fill in the name, enter a description if necessary, and click the **[ACTIVATE]** button.

The Uninstall window with the filled-in data

The [Uninstall](#) action will be in the cluster's list. The action will start running.

The Uninstall action is running

When the action is complete, the **Uninstall** button will be replaced by the **[RESTART]**, **[RESTORE]**, **[RESTORE]** and **[UPGRADE]** buttons.

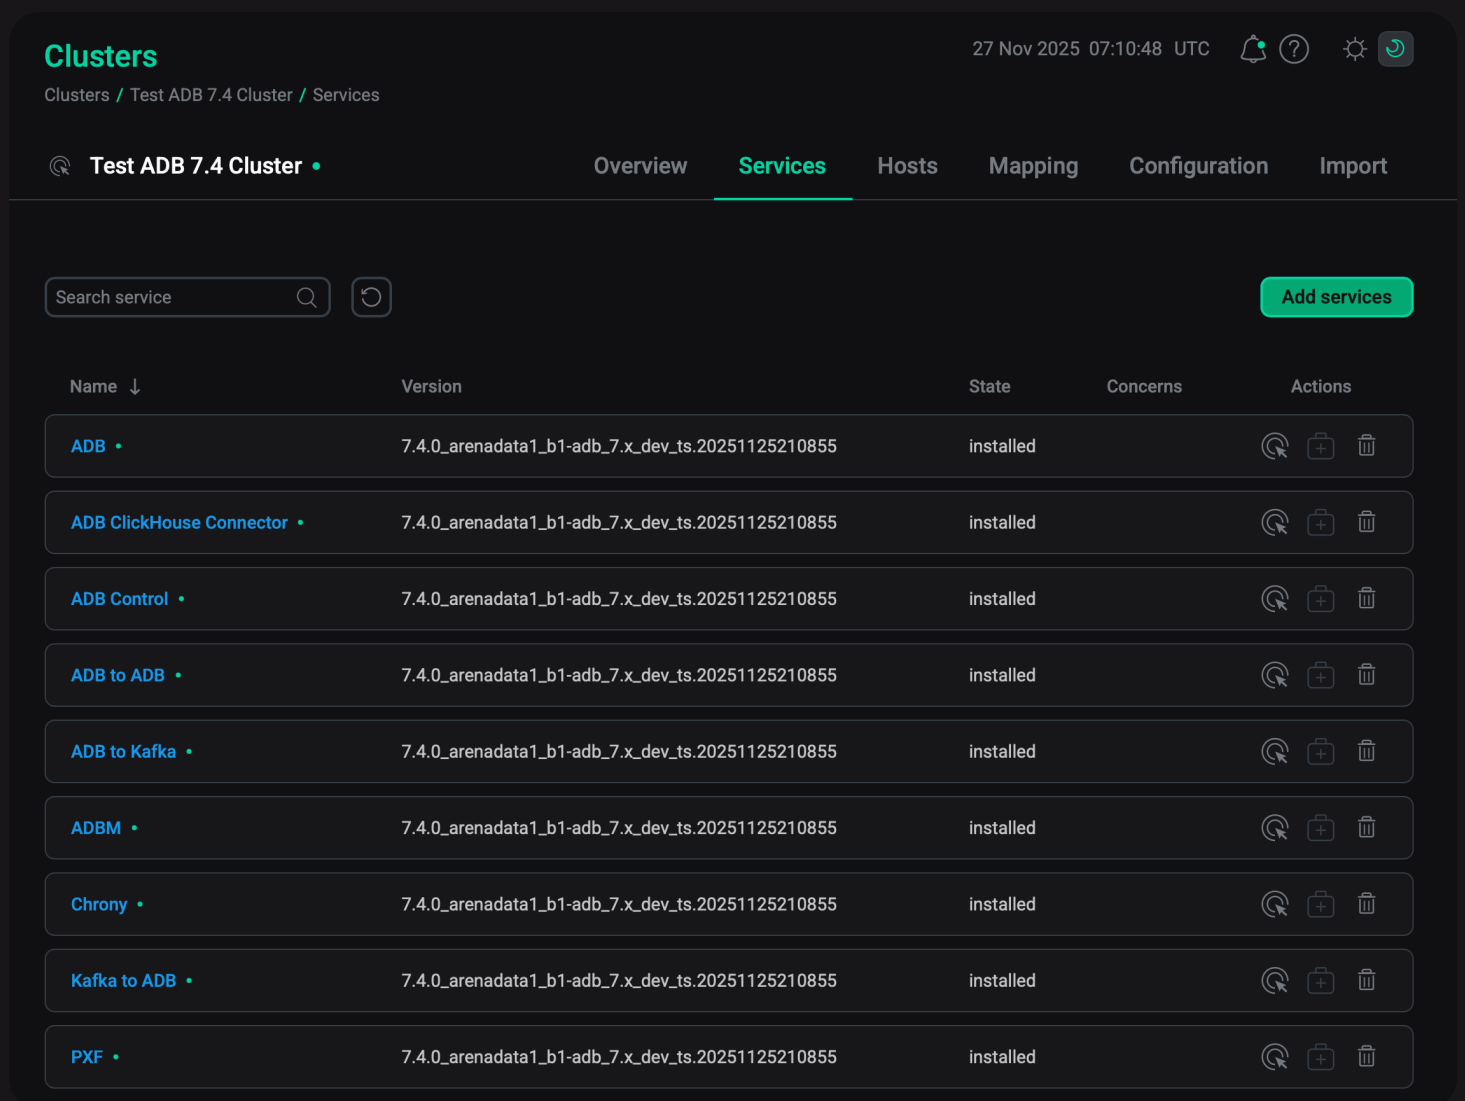
The Uninstall action is complete

Service actions

Anton Vasilev

To Table of Contents

ADCM UI provides actions to manage services. The actions are available on the ***Services*** tab. To open this tab, click an ADB cluster name on the ***Clusters*** page and switch to the ***Services*** tab.



ADB cluster services in the ADCM interface

Refer to ADCM documentation for an overview of the ***Services*** tab and common actions.

Refer to the following articles that describe actions of ADB cluster services:

- ADB
- ADB Control
- ADBM
- PXF
- Connectors
- Chrony

ADB service actions

Contents

[To Table of Contents]

- Create database
- Create role
- Enable auto core dump
- Disable auto core dump
- Enable mirroring
- Install diskpeta
- Install MADBs
- Install PostDB
- Architecture
  - Rank tables for redistribution
  - Pre-selection factor
  - Redistribution
- Run redistribution
- Run SQL
- Start
- Stop
- Manage tablespace

Create database

Before creating a database, you must first add the service type **ADB**.

Unlike normal environments, the service is not required to be initialized before creating ADB instances. You can use the command `dbs -l` to check the service list and confirm that ADB is present.

```
[root@node1 ~]# dbs -l
service_name  service_type  service_version  service_path
------------  ------------  ---------------  ------------
ADB           ADB           V1.0.0           /opt/antdb/adb
```

It is the ADB scenario that must be set to **QUANTITY**.

```
[root@node1 ~]# dbs -s
scenario
--------
QUANTITY
```

Create a new database:

```
[root@node1 ~]# dbs -c
name  type  charset  timezone  time_format  date_format  timestamp_format  timestamp_tz_format  interval_ds_format  interval_ym_format  default_tablespace  default_temporary_tablespace  extent_management  segment_management  flush_log_at_commit  sql_compatibility  sql_inherit  sql_ignore  sql_foreign_key_check  sql_unique_check  sql_trigger  sql_autocommit  sql_identified_by_case_sensitive  sql_mandatory_password_complexity  sql_password_reuse_time  sql_password_reuse_max  sql_password_lock_time  sql_password_grace_time  sql_password_life_time  sql_password_min_length  sql_password_max_length  sql_password_min_uppercase  sql_password_min_lowercase  sql_password_min_digits  sql_password_min_special_chars ADB Control service actions

Anton Vasilev

Contents

To Table of Contents

Install

Reinstall

Reconfigure & Restart

Start

Stop

Uninstall

This article describes the actions available for the ADB Control service in the ADCM web interface.

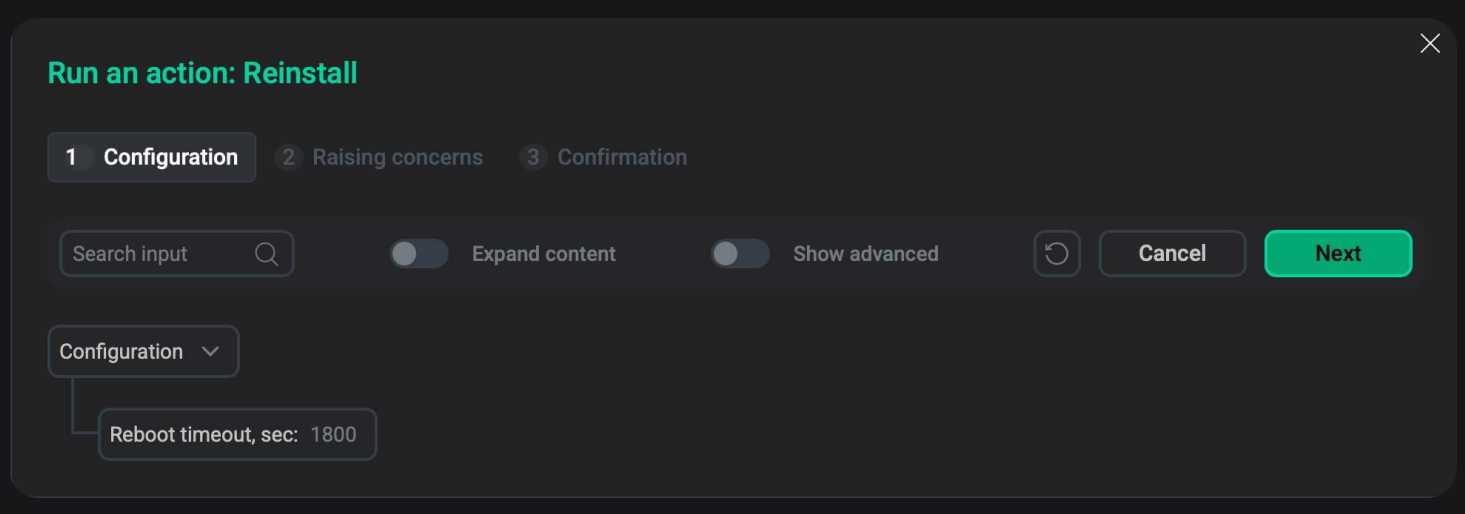
Install

Installs the ADB Control service. This action is available only if a service has been added but not yet installed.

Reinstall

Reinstalls the ADB Control service.

On the ***Configuration*** tab of the window that opens, in the ***Reboot timeout, sec*** field, enter the timeout to wait for hosts to restart (in seconds). The default value is `1800`. The value must be at least `600`.



The Reinstall window

Reconfigure & Restart

Updates the service configuration according to the configuration settings and restart the service.

In the window that opens, use the ***Unlock ADB Control db*** flag to determine what to do with database locks that may occur if a migration failed. When the flag is set to `true`, ADB Control releases the locks and makes its database available for migrations. The default value is `false`: preserve locks to avoid potentially conflicting migrations.

Start

Starts the ADB Control service.

Stop

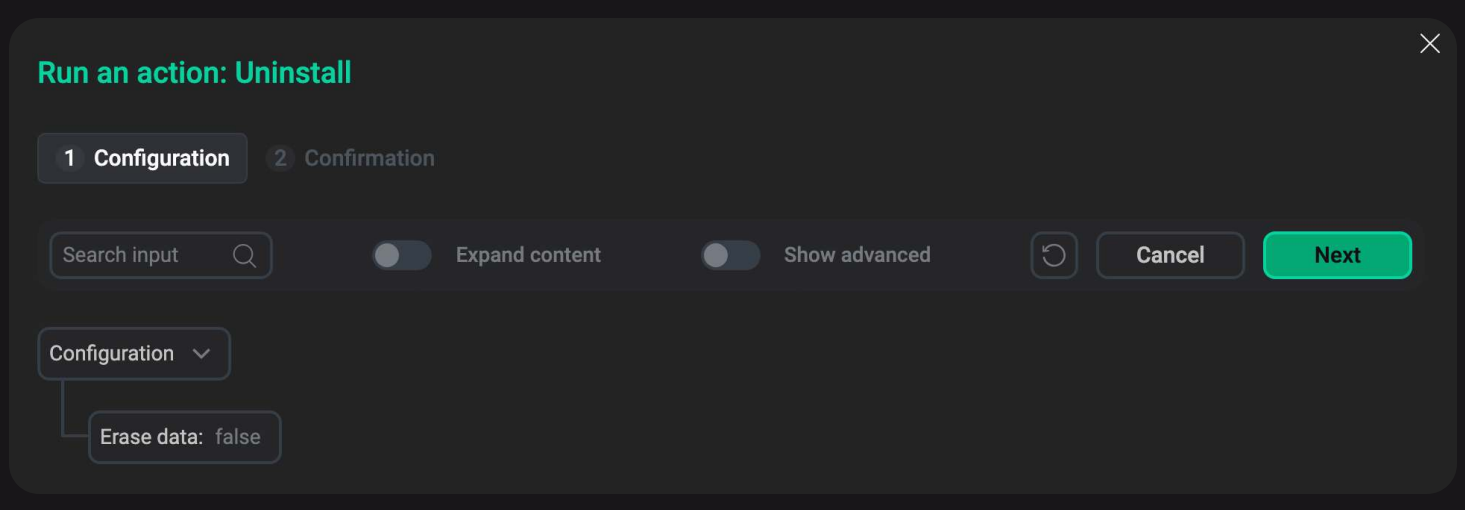
Stops the ADB Control service.

Uninstall

Uninstalls the ADB Control service. In the window that opens, use the ***Erase data*** flag to select whether you need to delete files associated with a service.

NOTE

The ADBM service depends on ADB Control. If you want to uninstall ADB Control, you have to uninstall ADBM first.



The Uninstall window

Install

Reinstall

Reconfigure & Restart

Start

Stop

Uninstall

This article describes the actions available for the Arenadata DB Backup Manager (ADBM) service in the ADCM web interface.

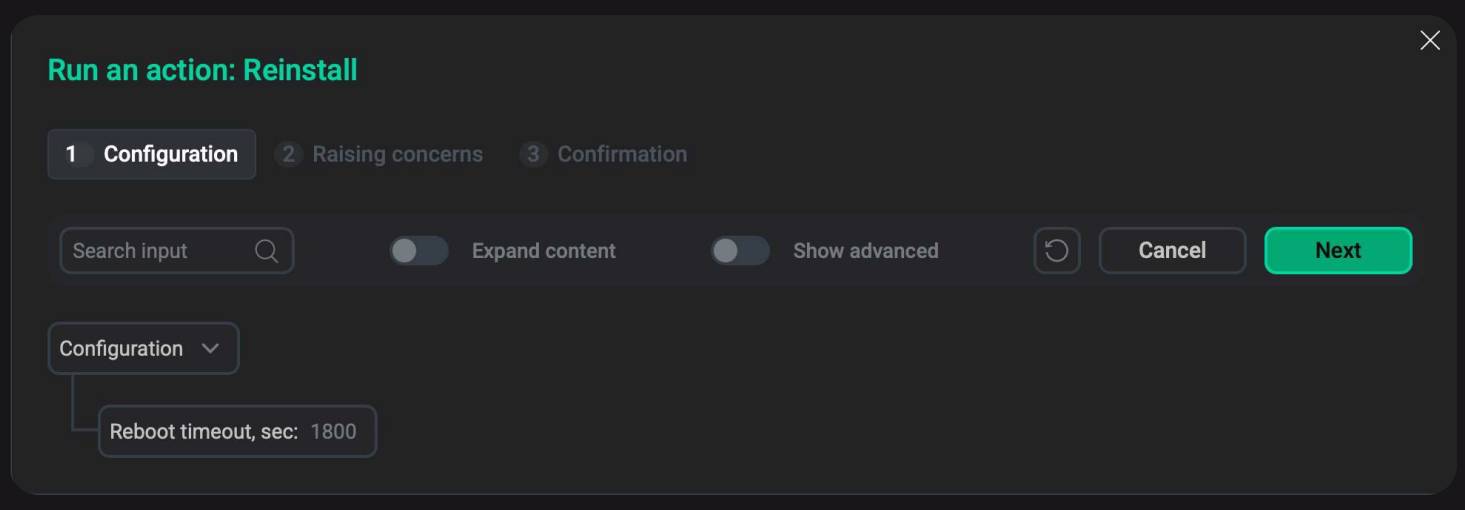
Install

Installs the ADBM service. This action is available only if a service has been added but not yet installed.

Reinstall

Reinstalls the ADBM service.

On the ***Configuration*** tab of the window that opens, in the ***Reboot timeout, sec*** field, enter the timeout to wait for hosts to restart (in seconds). The default value is `1800`. The value must be at least `600`.



The Reinstall window

Reconfigure & Restart

Updates the service configuration according to the configuration settings and restart the service.

In the window that opens, use the ***Unlock adbm db*** flag to determine what to do with database locks that may occur if a migration failed. When the flag is set to `true`, ADBM releases the locks and makes its database available for migrations. The default value is `false`: preserve locks to avoid potentially conflicting migrations.

Start

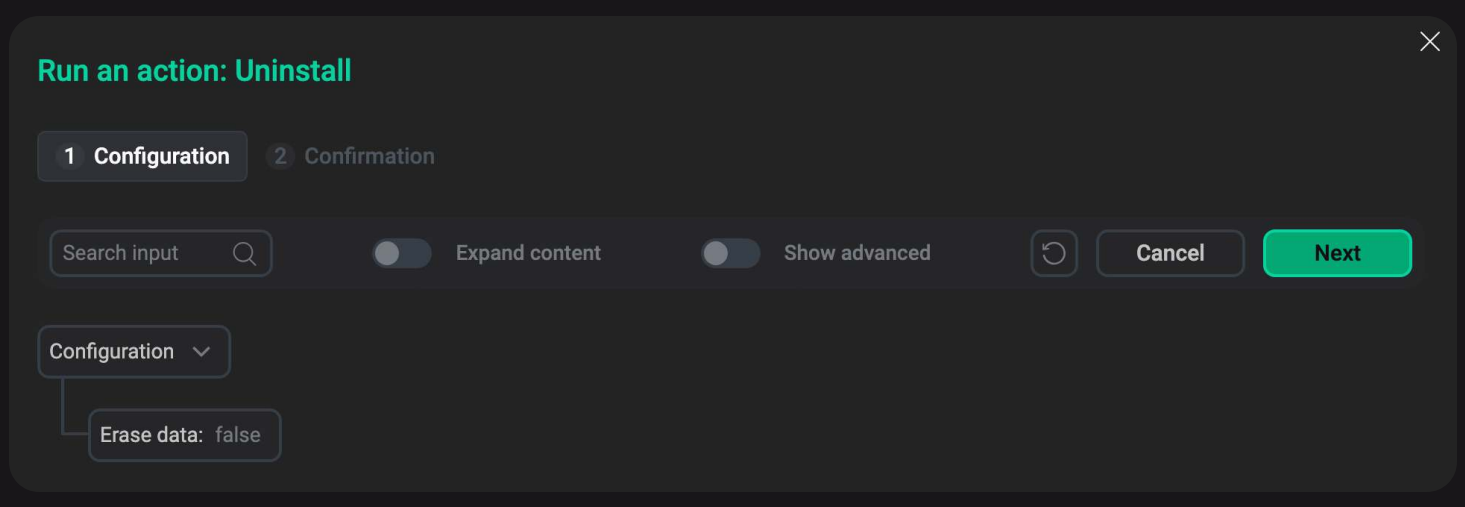
Starts the ADBM service.

Stop

Stops the ADBM service.

Uninstall

Uninstalls the ADBM service. In the window that opens, use the ***Erase data*** flag to select whether you need to delete files associated with a service.



The Uninstall window

PXF service actions

Install

Reconfigure

Restart

Start

Stop

Uninstall

This article describes the actions available for the PXF service in the ADCM web interface.

Install

Installs the PXF service. This action is available only if a service has been added but not yet installed.

Reconfigure

Updates the service configuration according to the configuration settings. If a changed parameter requires a restart, the action restarts the service.

Restart

Restarts the PXF service.

Start

Starts the PXF service.

Stop

Stops the PXF service.

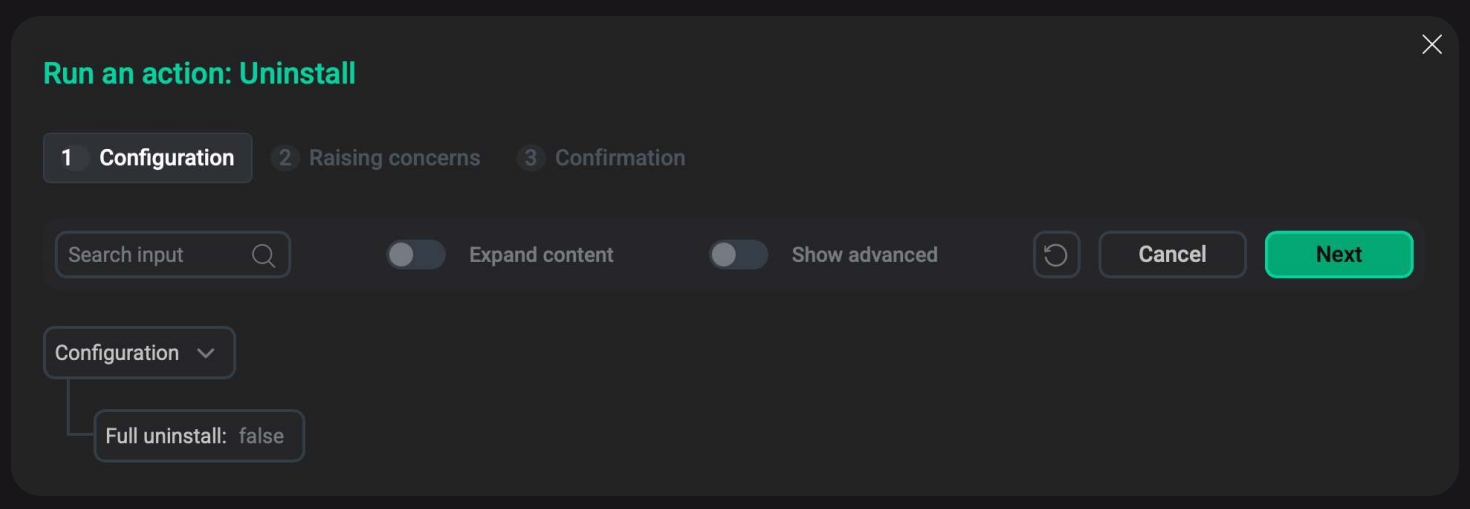
Uninstall

Uninstalls the PXF service.

NOTE

The ADB to Kafka and ADB ClickHouse connectors depend on the PXF service. You cannot uninstall PXF if you use these connectors.

In the window that opens, set the ***Full uninstall*** flag to `true` if you want to delete all PXF-related data: configuration files, the `pxf` user, the `pxf` and `pxf_fdw` database extensions, and objects that depend on these extensions. The default value is `false`.



The PXF → Uninstall window

Connector service actions

Install

Reinstall

Uninstall

The actions described below are available for the following connector services:

- ADB ClickHouse Connector
- ADB to Kafka Connector
- Kafka to ADB Connector
- ADB to ADB Connector

Install

Installs the connector service. This action is available only if a service has been added but not yet installed.

Reinstall

Reinstalls the connector service.

Uninstall

Uninstalls the connector service.

Chrony service actions

Anton Vasilev

Contents

To Table of Contents

Install

Add/remove chronys component

Reinstall

Uninstall

The Chrony service synchronizes a system clock within the cluster. Segment hosts get the time from the coordinator host. This article describes the actions available for the Chrony service in the ADCM web interface.

Install

Installs the Chrony service. This action is available only if a service has been added but not yet installed.

After installation, you can check the current time sources that are used in a host with the following command:

```
$ chronyc sources
```

For example, if the command is run on a segment host, the output shows that the coordinator host is used for synchronization and the standby coordinator is used as a backup source:

```
MS Name/IP address         Stratum Poll Reach LastRx Last sample
===============================================================================
^* mdw                          10   9   377   411    -82us[  -98us] +/-  271us
^- smdw                         11   9   377    76   -606us[ -606us] +/- 1326us
```

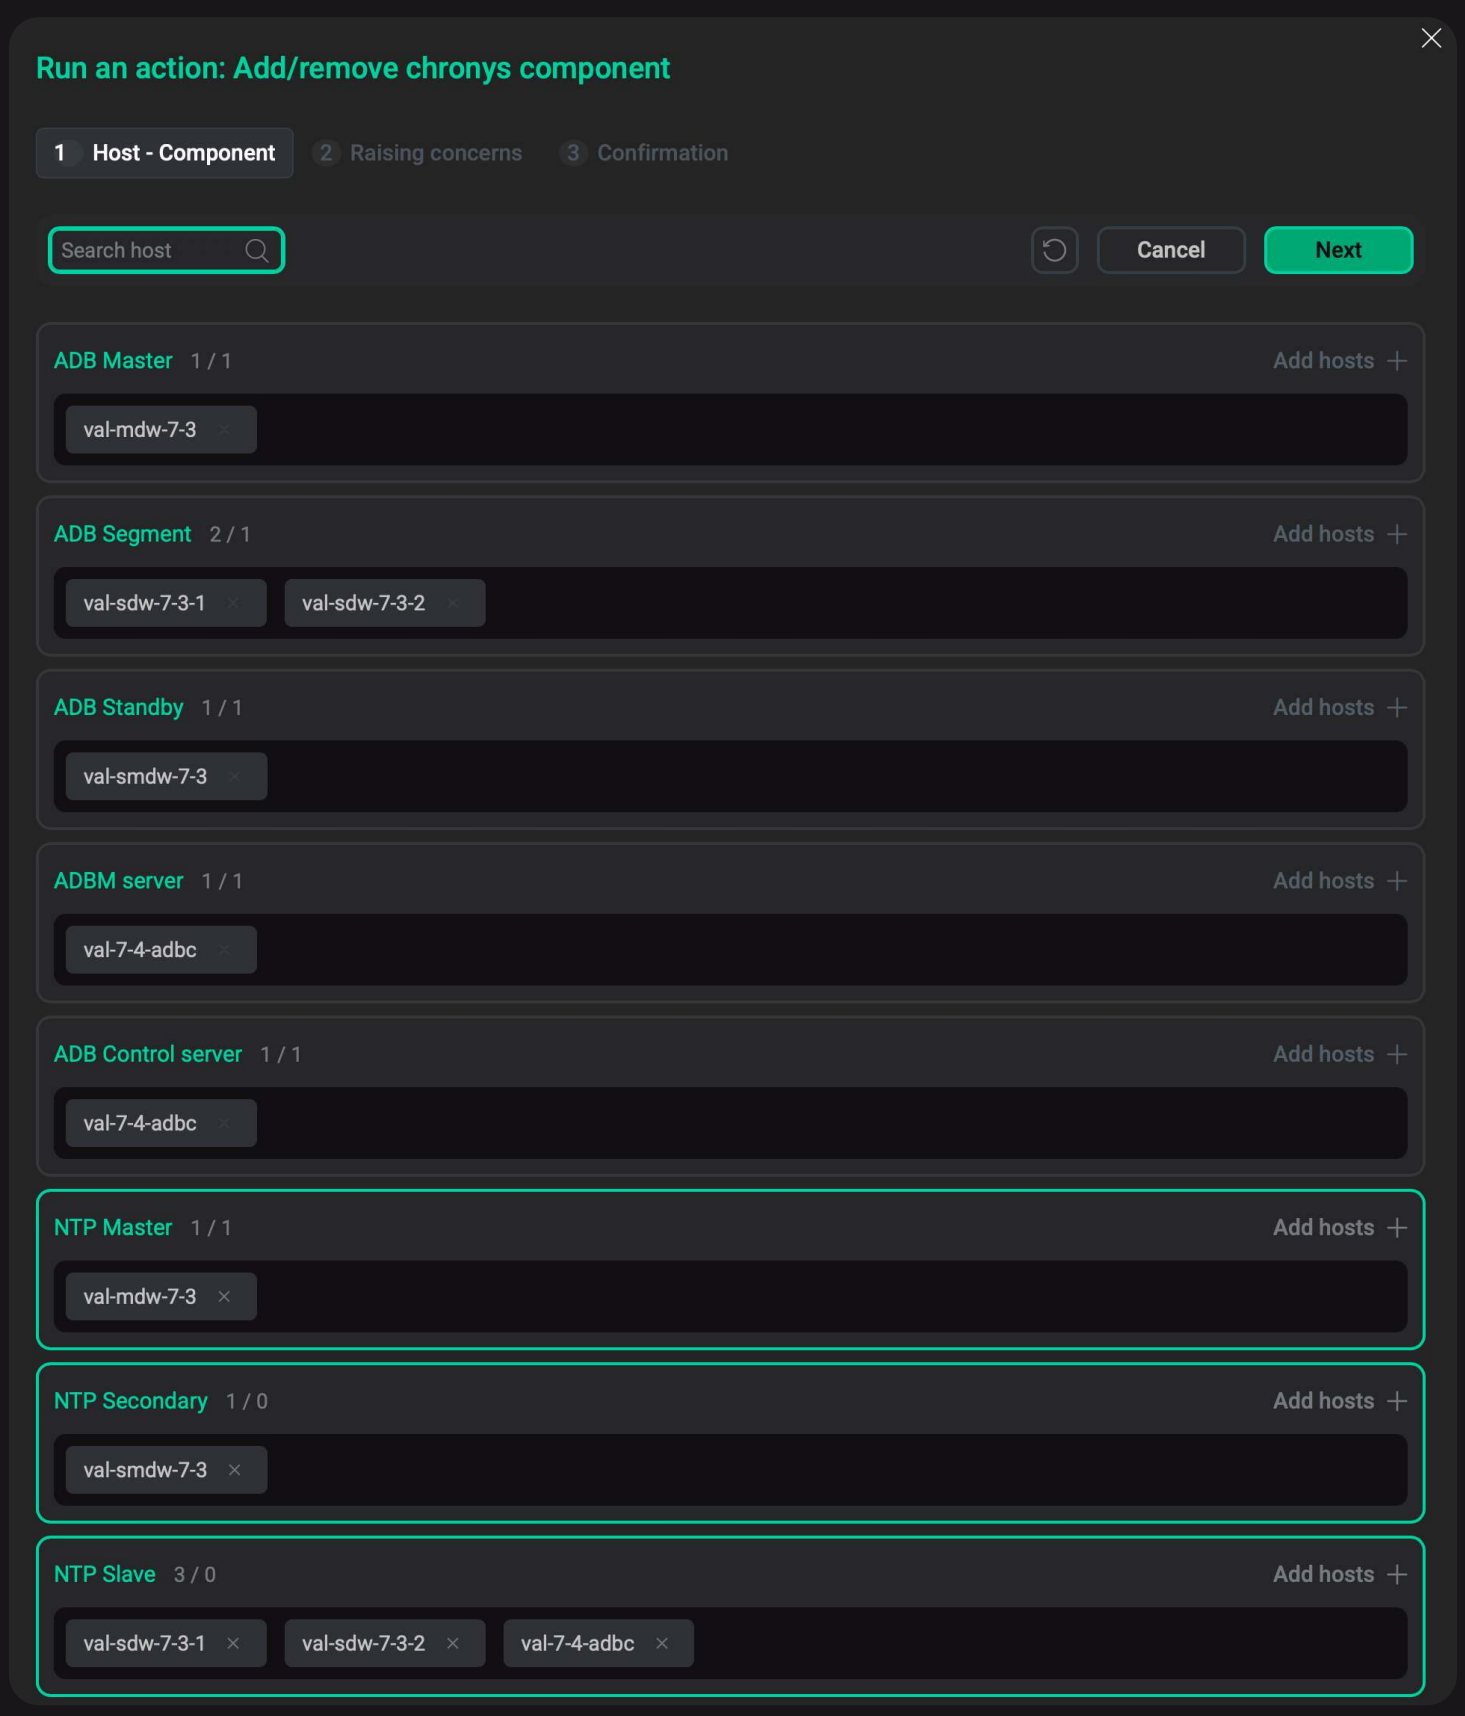
Add/remove chronys component

Allows you to change host-component mapping for Chrony: install it on the selected hosts or remove it.

In the window that opens, click ***Add hosts*** in the ***NTP Master***, ***NTP Secondary***, or ***NTP Slave*** section and select hosts on which you want to install Chrony.

NOTE

If you use Chrony, it should be installed on every cluster host.



The Add/remove chronys component window

Reinstall

Reinstalls the Chrony service.

Uninstall

Uninstalls the Chrony service.

Configure DBMS via GUCs

To Table of Contents

Overview

Server configuration parameters (also known as **Grand Unified Configuration, GUC**) allow ADB administrators to manage the DBMS cluster and all configuration. Many of these parameters have the same names and behaviours as in PostgreSQL.

NOTE
To see the full list of server configuration parameters, refer to Postgresql documentation.

The main GUC features are listed below:

- Parameter names and values are case-insensitive.
- Some parameters' value is a set of the following types: boolean, integer, floating point, enum, or string.
- Boolean values may be specified as:
  - **TRUE**, **ON**, **YES**, **TRUE**, **1**
  - **FALSE**, **OFF**, **NO**, **0**

- Each parameter's value specified in the same way as its string representation, but are limited by the specified set of values.
- For those parameters that specify the memory size, we can use the following size units:
  - **kB**: kilobytes
  - **MB**: megabytes
  - **GB**: gigabytes

  Remember that the multiplier for memory units is **1024**, not **1000**.
- For those parameters that specify time values, you can use the following time units:
  - **ms**: milliseconds
  - **s**: seconds
  - **min**: minutes
  - **h**: hours
  - **d**: days
- When specifying a memory in the parameter, unit-less by value in single quotes **''** and do not use any spaces between the value and the unit-size. For example:

```
SET effective_cache_size = '32kB';
```

Set parameters

Every server configuration parameter belongs to one of the categories see the list of the functions concerns in the Greenplum documentation(s), which define timeliness on who and how can change the parameter. Some parameters can be changed in more than one way.

session or system

This classification determines whether the parameter can be changed "on the fly" (without the **SIGHUP** signal) and the configuration file should.

- **session**: parameters of this type can be changed "on the fly" at one of the following levels:
  - database:

    ```
    ALTER DATABASE mydb SET parameter = mydbvalue;
    ```

  - database and role:

    ```
    ALTER ROLE myrole_name IN DATABASE <database_name> SET <parameter> = myrolevalue;
    ```

  - role:

    ```
    ALTER ROLE myrole_name SET <parameter> = myrolevalue;
    ```

  - database:

    ```
    ALTER DATABASE <database_name> SET <parameter> = myrolevalue;
    ```

  You can also define session parameters at the session level - via the postgresql.conf file (or using the **gpconfig** utility). In this case, session parameters cannot be applied "on the fly" and require a restart of the entire Greenplum system. See the Postgresql documentation for more information.

  If a session parameter is set at multiple levels, then the most specific setting has a higher precedence. For example, the parameter value that is defined at the session level will override the database default. The value defined at the database level will override the value that is specified in the postgresql.conf file on the coordinator.

- **system**: parameters of this type can only be changed via the postgresql.conf file (using the **gpconfig** utility). You cannot alter these parameters "on the fly". To define a system parameter value, edit the file postgresql.conf file and then use the **gpstop --reload** utility to upload the changes to all the Greenplum Database(s).

  For a list of parameters values in coordinator only, see the command list of **gpconfig** subsection.

```
$ gpconfig -c <parameter> -v <value> --coordinatoronly
```

> **CAUTION**
> This command cannot be applied to the **gp_default_storage_options** parameter, despite this parameter belongs to the system category. It also cannot be applied to any parameter that is classified as restricted. Restricted parameters have names that begin with the **gp_default_storage_options** prefix (search for DEFAULT on postgresql.conf documentation) and especially those, which are not shown by default.

- Set the parameter value on all segments (including coordinator):

```
$ gpconfig -c <parameter> -v <value>
```

  this will have values with the specified value on segment hosts and coordinator.

- Set the parameter value on segments only:

```
$ gpconfig -c <parameter> -v <value_segments> -m <value_coordinator>
```

- Comment the parameter out of configuration files, thus restoring its default value:

```
$ gpconfig -r <parameter>
```

coordinator or local

This classification applies to parameters which values are changed via the postgresql.conf file (system or session at the system level).

- **coordinator**: parameters of this type should be set in the configuration file of the coordinator instance. The values for these parameters are then passed on to generally to segments at the time.
- **local**: parameters of this type should be set in the configuration file of every segment (including coordinator). Each segment looks through its own configuration file to get the parameter value. postgresql.conf file (search for **CONFIG** in the file) is an example for this parameter.

restart or reload

This classification applies to parameters which values are changed via the postgresql.conf file (system or session at the system level).

- **restart**: parameters of this type requires a DBMS restart:

```
$ gpstop -ar -a
```

- **reload**: parameters of this type do not require a DBMS restart and can be refreshed by just reloading the server configuration file:

```
$ gpstop -u -a
```

superuser

Parameters of this type can only be set by a database superuser. Regular users cannot change values of such parameters.

read only

Parameters of this type cannot be set by any user (neither a regular database user nor a superuser). You can read the current values of such parameters but not alter them.

Get parameters

To show the current parameter value, use one of the following ways:

- If you are **SUPER** user or other roles/ segments, use the **SHOW <parameter(s)>** command. For example:

```
SHOW effective_cache_size;
```

  The result can be like:

```
 effective_cache_size
----------------------
 128000kB
(1 row)
```

> **IMPORTANT**
> Some parameters' full value will not be shown by basic the **SHOW** command (take into account the priority of settings). The answer should be the highest precedence, the system level – if reduced one.

- To get the parameter value that is defined in the postgresql.conf file (on the system level), log out from **psql** or any other client and run the following command: **gpconfig -s <parameter>**. This command shows the parameter values, separately for coordinator and segments. If you choose another value on all segments and coordinator, it should be the same:

```
$ gpconfig -s effective_cache_size

```

  Result:

```
Values on all segments are consistent
GUC : effective_cache_size
Coordinator value: 128000kB
Segment value: 128000kB
```

- Connect to the database and run the command **psql**. Use the command **SHOW** to see the current value:

```
psql -tAc 'SHOW <parameter>;' <db_name>
```

  For example:

```
psql -tAc 'SHOW effective_cache_size;' mydb
```

  Result:

```
128000kB
```

- Get the current parameter value:

```
SHOW myparameter;
```

  Result:

```
myvalue
```

- Change the parameter value to **off** at the session level:

```
SET myparameter = off;
```

  Result:

```
SET
```

- Get the current parameter value again:

```
SHOW myparameter;
```

  The value has changed:

```
 myparameter
-------------
 off
(1 row)
```

- Log out of **psql** or any other client and you see:

```
\q
```

- Connect to the database as **psql** or any other client program):

```
$ psql mydb
```

- Get the current parameter value again:

```
SHOW myparameter;
```

  If another sessions, the parameter still has a default value:

```
 myparameter
-------------
 myvalue
(1 row)
```

> **Session parameters (database-level)**
> Below is an example of changing the **gp_interconnect_queue_depth** parameter. The parameter has the **coordinator**, **session**, **reload** classification. To change the parameter value at the database level, do the following:
>
> 1. Connect to the ADB coordinator host (for example, via SSH) and log in under the default user (**gpadmin**):
>
> ```
> $ sudo su - gpadmin
> ```
>
> 2. Connect to the database as **psql** (or any other client program):
>
> ```
> $ psql mydb
> ```
>
> 3. The output is:
>
> ```
> psql (12.12)
> Type "help" for help.
> ```
>
> 4. Get the current parameter value:
>
> ```
> SHOW gp_interconn;
> ```

> ```
>
> 12. Connect to the database as **psql** or any other client program):
>
> ```
> $ psql mydb
> ```
>
> 13. Get the current parameter value again:
>
> ```
> SHOW gp_interconnect_address_type;
> ```
>
> The value has changed:
>
> ```
> gp_interconnect_address_type
> ----------------------------
> TCP
> (1 row)
> ```
>
> **TIP**
> When changing the session configuration parameter at the database level, do not forget to restart the current database session. Otherwise, you cannot see the changes.
>
> 14. Connect to any other database:
>
> ```
> $ psql template1
> ```
>
> Result:
>
> ```
> You are now connected to database "template1" as user "gpadmin".
> ```
>
> 15. Check the current parameter value again:
>
> ```
> SHOW gp_interconnect_address_type;
> ```
>
> If another database, the parameter still has a default value:
>
> ```
> gp_interconnect_address_type
> ----------------------------
> IP
> (1 row)
> ```

> **System parameter (coordinator and reload)**
> Below is an example of changing the **gp_interconnect_queue_depth** parameter. The parameter has the **coordinator**, **system**, **reload** classification. To change the parameter value, do the following:
>
> 1. Connect to the ADB coordinator host (for example, via SSH) and log in under the default user (**gpadmin**):
>
> ```
> $ sudo su - gpadmin
> ```
>
> 2. Get the current parameter value:
>
> ```
> $ gpconfig -s gp_interconnect_queue_depth
> ```
>
> Result:
>
> ```
> Values on all segments are consistent
> GUC : gp_interconnect_queue_depth
> Coordinator value: 4096
> Segment value: 4096
> ```
>
> 3. Change the parameter value to **2048** on coordinator:
>
> ```
> $ gpconfig -c gp_interconnect_queue_depth -v 2048 --coordinatoronly
> ```
>
> Result:
>
> ```
> 20221011:07:55:05:029470 gpconfig:mdw:gpadmin-[INFO]:-completed successfully with parameters '-c gp_interconnect_queue_depth -v 2048 --coordinatoronly'
> ```
>
> 4. Get the current parameter value again:
>
> ```
> $ gpconfig -s gp_interconnect_queue_depth
> ```
>
> They are still the same:
>
> ```
> Values on all segments are consistent
> GUC : gp_interconnect_queue_depth
> Coordinator value: 4096
> Segment value: 4096
> ```
>
> 5. Reload the configuration file:
>
> ```
> $ gpstop -u -a
> ```
>
> 6. Check the current parameter values again:
>
> ```
> $ gpconfig -s gp_interconnect_queue_depth
> ```
>
> The value is changed for coordinator:
>
> ```
> Values on all segments are consistent
> GUC : gp_interconnect_queue_depth
> Coordinator value: 2048
> Segment value: 4096
> ```
>
> As the **gp_interconnect_queue_depth** parameter belongs to the **coordinator** category, it is not required to change the parameter value on other segments.

> **System parameter (local and restart)**
> Below is an example of changing the **gp_interconnect** parameter. The parameter has the **local**, **system**, **restart** classification. To change the parameter value, do the following:
>
> 1. Connect to the ADB coordinator host (for example, via SSH) and log in under the default user (**gpadmin**):
>
> ```
> $ sudo su - gpadmin
> ```
>
> 2. Get the current parameter values:
>
> ```
> $ gpconfig -s max_connections
> ```
>
> Result:
>
> ```
> Values on all segments are consistent
> GUC : max_connections
> Coordinator value: 150
> Segment value: 150
> ```
>
> 3. Change the parameter value on coordinator to **200** and on segment hosts - to **300**:
>
> ```
> $ gpconfig -c max_connections -v 300 -m 200
> ```
>
> Result:
>
> ```
> 20221011:07:59:25:029970 gpconfig:mdw:gpadmin-[INFO]:-completed successfully with parameters '-c max_connections -v 300 -m 200'
> ```
>
> 4. Get the current parameter value again:
>
> ```
> $ gpconfig -s max_connections
> ```
>
> They are still the same:
>
> ```
> Values on all segments are consistent
> GUC : max_connections
> Coordinator value: 150
> Segment value: 150
> ```
>
> 5. Restart the system:
>
> ```
> $ gpstop -ra
> ```
>
> 6. Check the current parameter values again:
>
> ```
> $ gpconfig -s max_connections
> ```
>
> The values are changed for coordinator and segments according to step 3:
>
> ```
> Values on all segments are consistent
> GUC : max_connections
> Coordinator value: 200
> Segment value: 300

Use ADB DDBoost plugin

Denis Barysheva

Contents

To Table of Contents

Overview
Installation and configuration
Usage examples
- gpbackup
- gprestore

Overview

ADB DDBoost is a plugin connector for native usage of the Dell EMC Data Domain storage system with Greenplum utilities for logical data backup (gpbackup) and restore (gprestore).

When the DDBoost plugin is used with **gpbackup** and **gprestore**, it connects to the Data Domain Platform, the plugin requires the *libDDBoost.so* library version 7.7, which is supplied as part of the Dell DDBoostSDK 7.7 package. This library is proprietary and should be obtained through Dell Support or Dell Data Domain representatives in your country. Due to deduplication of data provided by the library, the DDBoost plugin allows you to significantly accelerate backup operations and reduce the physical storage usage.

NOTE

- For more information on the ADB DDBoost plugin architecture, advantages, and load testing results, see Arenadata technical blog.
- The DDBoost plugin is available in the Enterprise version of ADB.

Installation and configuration

To install the ADB DDBoost plugin, follow the steps:

1. Install the adb-ddp-plugin package **on all cluster hosts** under the user with `sudo` privileges. Below is an example of installation via the APT package manager:

```
$ sudo apt install adb-ddp-plugin
```

As a result of the successful command execution, a plugin executable file is added to the following location: *$GPHOME/bin/adb_ddp_plugin*.

2. Put the *libDDBoost.so* library to the lib directory on **all cluster hosts**.
3. Connect to the ADB **coordinator host** under the `gpadmin` user.

```
$ sudo su - gpadmin
```

4. On the **coordinator host**, create a YAML configuration file in the */home/gpadmin* directory (for example, *adb_ddp_plugin.yaml*). A file structure and its description are given below:

```
executablepath: /usr/lib/gpdb/bin/adb_ddp_plugin
options:
  hostname: "testhost"
  username: "testuser"
  password: "XXXXXXXXXX"
  storage_unit: "Testunit"
  directory: "testdir"
  write_buffer_size: "1048576"
  read_buffer_size: "1048576"
  log_level: "DEBUG"
  log_path: "/home/gpadmin"
```

Fields of the plugin configuration file

Name	Description	Default	Required
executablepath	An absolute path to the plugin in the file system of ADB hosts (along with the plugin executable file name). The plugin should be installed on all cluster hosts in the same directory. The default path to the plugin executable file is *$GPHOME/bin/adb_ddp_plugin*	—	Yes
hostname	An IP address or name of the host that provides operations with DDBoost. Can contain no more than 30 characters	—	Yes
username	A name of the user who is granted permissions to work with DDBoost. The user is configured on the DDBoost side. This is not the operating system nor ADB user. Can contain no more than 30 characters	—	Yes
password	A password of the user who is granted permissions to work with DDBoost	—	Yes
storage_unit	A name of the storage unit that is configured on the DDBoost side	—	Yes
directory	A name of the directory in the DDBoost file system. That directory is used to store all backup files created when the **gpbackup** utility is run with the DDBoost plugin. In the */<storage_unit>/<directory>* folder, the plugin automatically creates all subdirectories corresponding to the creation date and time of each backup: */<storage_unit>/<directory>/YYYYMMDD/YYYYMMDDHHmmSS/*	—	Yes
write_buffer_size	A buffer size for writing data to DDBoost (in bytes). Values from the following range are allowed: 64 <= write_buffer_size <= 1048576	—	Yes
read_buffer_size	A buffer size for reading data from DDBoost (in bytes). Values from the following range are allowed: 64 <= read_buffer_size <= 1048576	—	Yes
log_level	A log level. Possible values: - `DEBUG` - `INFO` - `NOTICE` - `WARN` - `ERROR` - `FATAL`	WARN	No
log_path	An absolute directory path to write plugin logs. The *adb_ddp_plugin.log* file is created in the specified directory when the plugin is used	*/home/gpadmin/gpAdminLogs*	No

Usage examples

gpbackup

To use the ADB DDBoost plugin when creating backups via the **gpbackup** utility, specify the `--plugin-config <yaml_path>` command argument, where `<yaml_path>` is an absolute path to the plugin configuration file in YAML format.

The following example shows how to back up one table of the **adb** database:

1. Connect to the **adb** database on ADB coordinator under the `gpadmin` user (for example, via `psql`). Using the `psql` command `\dt` ensure the required table `public.test` in the given example) exists in the database:

```
\dt
```

Result:

```
                List of relations
 Schema |    Name     | Type |  Owner  |      Storage
--------+-------------+------+---------+-------------------
 public | spatial_ref_sys | table | gpadmin | heap
 public | test        | table | gpadmin | heap
 public | test2       | table | gpadmin | ao_column
 public | test3       | table | gpadmin | ao_column
(4 rows)
```

2. Disconnect from **adb** and run `gpbackup` with the `--plugin-config` parameter under the `gpadmin` user. Note that the `--include-table` parameter allows you to back up one table:

```
$ gpbackup --dbname adb --no-compression --single-data-file --include-table public.test --plugin-config
/home/gpadmin/adb_ddp_plugin.yaml
```

TIP

When the DDBoost plugin is used along with `gpbackup`, it is recommended to set the backup mode 'all segment tables – one file' (`--single-data-file`). Do not use the parallel backup mode (`--jobs`) because of its extremely low write performance.

In the command output, note the backup timestamp, which will be used as the backup directory and will be needed when restoring data:

```
[INFO]:-Backup Timestamp = 20251112160114
```

If the data backup succeeds, the command output ends with the following message:

```
[INFO]:-Backup completed successfully
```

3. Ensure that the backup files are generated and stored on the selected Data Domain Platform server. To do this, open the */<storage_unit>/<directory>/YYYYMMDD/YYYYMMDDHHmmSS* directory on the server, where:

- `<storage_unit>` and `<directory>` – values of the corresponding fields from the plugin YAML configuration file.
- `YYYYMMDD` – backup creation date.
- `YYYYMMDDHHmmSS` – backup creation date and time. It is a timestamp that will be used as the `--timestamp` value when restoring data from the current backup.

```
$ ls /<storage_unit>/<directory>/20251112/20251112160114/
```

The directory contents are as follows:

```
gpbackup_0_20251112160114                          gpbackup_3_20251112160114
gpbackup_0_20251112160114_toc.yaml                 gpbackup_3_20251112160114_toc.yaml
gpbackup_1_20251112160114                          gpbackup_4_20251112160114
gpbackup_1_20251112160114_toc.yaml                 gpbackup_4_20251112160114_toc.yaml
gpbackup_20251112160114_config.yaml                gpbackup_5_20251112160114
gpbackup_20251112160114_metadata.sql               gpbackup_5_20251112160114_toc.yaml
gpbackup_20251112160114_plugin_config.yaml         gpbackup_6_20251112160114
gpbackup_20251112160114_report                     gpbackup_6_20251112160114_toc.yaml
gpbackup_20251112160114_toc.yaml                   gpbackup_7_20251112160114
gpbackup_2_20251112160114                          gpbackup_7_20251112160114_toc.yaml
gpbackup_2_20251112160114_toc.yaml
```

On the coordinator host, in the *$COORDINATOR_DATA_DIRECTORY/backups/YYYYMMDD/YYYYMMDDHHmmSS* directory, a report about the completed backup is available with information about the number of objects in the backup copy:

```
$ cat /data1/master/gpseg-1/backups/20251112/20251112160114/gpbackup_20251112160114_report
```

Example of a report for a successful one-table backup

```
Greenplum Database Backup Report

timestamp key:          20251112160114
gpdb version:           7.3.0+dev.845.g784d6bfe9ef build 254+git784d6bfe
gpbackup version:       1.30.4

database name:          adb
command line:           gpbackup --dbname adb --no-compression --single-data-file --include-table public.test --plugin-config
/home/gpadmin/adb_ddp_plugin.yaml
compression:            None
plugin executable:      adb_ddp_plugin
backup section:         All Sections
object filtering:       Include Table Filter
includes statistics:    No
data file format:       Single Data File Per Segment
incremental:            False

start time:             Wed Nov 12 2025 16:01:14
end time:               Wed Nov 12 2025 16:01:52

tables              1
triggers            0
views               0
```

gprestore

To use the ADB DDBoost plugin when restoring data via the **gprestore** utility, specify the `--plugin-config <yaml_path>` command argument, where `<yaml_path>` is an absolute path to the plugin configuration file in YAML format.

The following example shows how to restore the `public.test` table, for which a backup was previously created:

1. Connect to the **adb** database on ADB coordinator under the `gpadmin` user (for example, via `psql`). Drop the `public.test` table:

```
DROP TABLE test;
```

2. Ensure the table does not exist via the `psql` command `\dt`:

```
\dt
```

Result:

```
                List of relations
 Schema |    Name     | Type |  Owner  |      Storage
--------+-------------+------+---------+-------------------
 public | spatial_ref_sys | table | gpadmin | heap
 public | test2       | table | gpadmin | ao_column
 public | test3       | table | gpadmin | ao_column
(3 rows)
```

3. Disconnect from **adb** and run **gprestore** with the `--plugin-config` parameter under the `gpadmin` user. Note that the `--timestamp` value should contain the backup creation timestamp in the `YYYYMMDDHHmmSS` format:

```
$ gprestore --timestamp 20251112160114 --plugin-config /home/gpadmin/adb_ddp_plugin.yaml --include-table public.test
```

If the data restore succeeds, the command output ends with the following message:

```
[INFO]:-Restore completed successfully
```

4. Connect to the **adb** database again and check that the `public.test` table is available:

```
\dt
```

Result:

```
                List of relations
 Schema |    Name     | Type |  Owner  |      Storage
--------+-------------+------+---------+-------------------
 public | spatial_ref_sys | table | gpadmin | heap
 public | test        | table | gpadmin | heap
 public | test2       | table | gpadmin | ao_column
 public | test3       | table | gpadmin | ao_column
(4 rows)
```

Work with arenadata_toolkit

Cluster management scripts
- Overview
- Example of a custom function for VACUUM

To Table Of Contents

When you install or ADB update the `arenadata_toolkit` extension is automatically created in the default database. The schema is used to collect information on cluster operations. The schema contains a set of tables that store the operation history and the `VACUUM` , `ANALYZE` commands that are launched on a schedule. Also, the `arenadata_toolkit` set of tools that store the operation history and the `arenadata_toolkit

Manage spill files

Daria Barysheva

Contents

To Table of Contents

- Overview
- Analyze spill files usage
- Manage spill files

Overview

Spill files (also known as **work files**) are created on disks if there is not enough memory to store temporary data when executing data queries. This temporary data may include `JOIN` hashes, sorting results, redistributed tables, etc. The directory for storing spill files can be defined via the server configuration parameter *temp_tablespaces*.

Since spill files are stored on the hard disk and the speed of reading/writing data from disks is several times slower than from RAM, the total execution time of queries grows. It can also increase the queues for resources from other users. Ideally, there should be no queries that generate spill files. However, a small number of spill files is allowed. In fact, spill files represent a flexible method of executing a query despite the limited amount of RAM. But you should avoid situations when there are too many spill files.

There are some typical cases when a large number of spill files can be generated:

- **Data skew is present in the queried data**. To see how to avoid it, refer to Recommendations on avoiding data skew.
- **The amount of memory allocated for the query is too low**. You can control the maximum memory size to be used by a query with the server configuration parameters `max_statement_mem` and `statement_mem`. You can also configure resource groups.
- **The query is not optimized**:
  - **DISTINCT is used on a large number of fields**. Every unique combination of columns specified in the `DISTINCT` clause is added to RAM. Accordingly, the more such combinations are detected, the faster the memory fills up and spill files are generated. It is recommended to limit the number of requested columns and avoid using huge size columns in the `DISTINCT` clause.
  - **ORDER BY is used**. Intermediate sorting results are initially stored in RAM. The larger the amount of data is to be sorted, the faster the generation of spill files begins. In Greenplum, it is not recommended to use sorting in queries, especially for large tables. Instead, it is better to sort the results directly in the data receiver (on the client side).
  - **A huge amount of data is processed without filters in the WHERE clause**. When performing `JOIN` queries, data from one of the tables is added to a hash table in RAM. Accordingly, if the requested data of this table is not filtered, the memory will overflow very quickly. It is recommended to use filters wherever possible, especially for dates and timestamptz. Even if you need to get results for the entire period, it is desirable to form several queries in short time intervals, after which you can combine the results using `UNION ALL`. This approach is more effective than trying to process the data in its entirety.
  - **When executing JOIN queries, a hash table is built on a larger of several tables**. When executing `INNER JOIN`, the hash table mentioned above is built on the basis of the table with the smallest size (in order to minimize RAM usage). However, when you use `LEFT JOIN` – the table defined on the right side is always taken as the basis for the hash table, regardless of its volume. It can lead to problems if this table is the largest in the pair. Therefore, pay attention to the order of all tables in data queries. Also try to minimize the number of extracted columns.

TIP

- Always try to reduce the number of spill files by changing queries, distribution policy, or memory configuration.
- If these methods do not help, you can change some server configuration parameters to limit the number of spill files and the disk space they use.

Analyze spill files usage

The default schema `gp_toolkit` contains views that show information about all the queries that are currently using spill files. These views can be useful for analyzing queries and for troubleshooting:

- `gp_workfile_entries` – shows query operators that use disk space for spill files on a segment at the current time. A single row corresponds to a single query operator.

  Structure

Column	Description
datname	The database name
pid	Process ID of the server process
sess_id	Session ID
command_cnt	Command ID of the query
username	The role name
query	The current query being running by the process
segid	A content identifier for a segment instance. Corresponds to `gp_segment_configuration.content`. For more information, see the ***System catalog tables*** → ***gp_segment_configuration*** section of the Tables overview article
slice	The query plan slice. Shows the portion of the query plan that is being run
optype	The type of the query operator that created the spill file
size	Spill files size (in bytes)
numfiles	The number of spill files created
prefix	The prefix used when naming a related spill files set

  Example:

```
SELECT * FROM gp_toolkit gp_workfile_entries;
```

  Result:

```
 datname | pid  | sess_id | command_cnt | username |                    query                    | segid | slice | optype |  size   | numfiles |  prefix
---------+------+---------+-------------+----------+---------------------------------------------+-------+-------+--------+---------+----------+----------
 adb     | 5332 |      65 |          42 | gpadmin  | SELECT DISTINCT(id1,id2,gen1,gen2) from t1; |    -1 |     0 | Sort   | 4292608 |        1 | Sort_1
(1 row)
```

- `gp_workfile_usage_per_query` – shows queries that use disk space for spill files on a segment at the current time. A single row corresponds to a single query.

  Structure

Column	Description
datname	The database name
pid	Process ID of the server process
sess_id	Session ID
command_cnt	Command ID of the query
username	The role name
query	The current query being running by the process
segid	A content identifier for a segment instance. Corresponds to `gp_segment_configuration.content`. For more information, see the ***System catalog tables*** → ***gp_segment_configuration*** section of the Tables overview article
size	Spill files size (in bytes)
numfiles	The number of spill files created

  Example:

```
SELECT * FROM gp_toolkit gp_workfile_usage_per_query;
```

  Result:

```
 datname | pid  | sess_id | command_cnt | username |                    query                    | segid |   size   | numfiles
---------+------+---------+-------------+----------+---------------------------------------------+-------+----------+----------
 adb     | 5332 |      65 |          42 | gpadmin  | SELECT DISTINCT(id1,id2,gen1,gen2) from t1; |    -1 | 20807680 |        1
(1 row)
```

- `gp_workfile_usage_per_segment` – shows the total size of disk space used for spill files on each segment at the current time. A single row corresponds to a single segment.

  Structure

Column	Description
segid	A content identifier for a segment instance. Corresponds to `gp_segment_configuration.content`. For more information, see the ***System catalog tables*** → ***gp_segment_configuration*** section of the Tables overview article
size	Spill files size (in bytes)
numfiles	The number of spill files created

  Example:

```
SELECT * FROM gp_toolkit gp_workfile_usage_per_segment;
```

  Result:

```
 segid |   size   | numfiles
-------+----------+----------
     5 |        0 |
    13 |        0 |
    10 |        0 |
    11 |        0 |
     1 |        0 |
     6 |        0 |
    12 |        0 |
     0 |        0 |
     2 |        0 |
     7 |        0 |
    15 |        0 |
     4 |        0 |
     8 |        0 |
     3 |        0 |
    -1 | 31752192 |        1
    14 |        0 |
     9 |        0 |
(17 rows)
```

NOTE

The views listed above are accessible to all users. However, non-superusers can get information only on the databases that they have permission to access.

Manage spill files

To limit the number of spill files and the disk space consumed by them, you can use several configuration parameters. Their description is given below.

Name	Description	Default value	Type
gp_workfile_limit_files_per_query	The maximum number of spill files allowed per query at each segment. If the limit is reached, the following error occurs: `ERROR: number of workfiles per query limit exceeded`. The `0` value allows an unlimited number of spill files	100000	coordinator session reload
gp_workfile_limit_per_query	The maximum disk size each query is allowed to use for spill files at each segment (in KB). If the limit is reached, the following error occurs: `ERROR: workfile per query size limit exceeded`. The `0` value means no limit	25000000	coordinator session reload
gp_workfile_limit_per_segment	The maximum total disk size that all running queries are allowed to use for spill files at each segment (in KB). If the limit is reached, the following error occurs: `ERROR: workfile per segment size limit exceeded`. The `0` value means no limit	50000000	local system restart
gp_workfile_compression	Specifies whether to use compression for spill files when a hash aggregation or hash join operation spills to disk during query processing. The default value `off` means no compression is used. Setting the value to `on` enables compression	off	coordinator session reload

IMPORTANT

- The default value of the `gp_workfile_limit_files_per_query` parameter (`100000`) is sufficient for the majority of queries. Before raising it, try to optimize your queries and distribution/memory options.
- Limiting the number or size of spill files prevents queries from disrupting the DBMS. But it also leads to termination of your queries when the limits are reached.
- Enabling compression via the `gp_workfile_compression` parameter can improve performance of the queries that generate spill files. But remember that data compression reduces the number of I/O operations at the expense of increased CPU usage.

Delete orphaned files in ADB

Daria Barysheva

Contents

To Table of Contents

Overview

Configuration

Overview

Orphaned files are data files that are not related to any database table. They can remain in the file system after a crash of some backend process associated with a transaction that creates a new table. Possible crash causes include hardware failures, lack of free disk space, and so on. As a result of successful recovery after failure, uncommitted changes are missing in the database (the new table does not exist in the system catalog), but data files of that table may remain on segment hosts. Over time, such abandoned files may increase in number, wasting valuable storage space. The process of searching for and deleting such files is time-consuming, and there are always risks associated with removing valuable data.

Starting with 6.29.0.3 in ADB 6 and 7.4.0 in ADB 7, DBMS supports automatic tracking and deletion of orphaned files at the DBMS core level in case of the transaction interruption. In previous ADB versions, data files were automatically deleted for those transactions that were aborted normally (via `ABORT`), but orphaned files could be deleted only manually (for example, by searching them via functions and views of the gp_check_functions extension).

The new approach to tracking and deleting orphaned files that is implemented in the ADB versions mentioned above is based on the following key concepts:

- In case of a commit or rollback of a transaction that creates a table, the DBMS core, like before, independently determines how to process the table data files in normal mode. In case of `ABORT`, files are deleted; in case of `COMMIT PREPARED` they remain.
- Only transactions in the `TRANSACTION_STATUS_IN_PROGRESS` status are considered as candidates for deleting orphaned files. The DBMS core suggests that transactions in that status can abort abnormally and leave orphaned files. Transactions in all other statuses are not considered, as they are processed in the standard way (see the previous point).
- The decision to delete a certain orphaned file is automatically made at the recovery startup.

IMPORTANT

- For more information on the causes of orphaned files, approaches to solving that problem in other DBMS, and implementation details from the ADB/Greengage DB team, see Deleting orphaned files in the technical blog.
- Remember that installation of the ADB versions mentioned above does not allow you to delete already existing orphaned files, but it will prevent them from being produced in the future.

Configuration

You can manage tracking and deleting orphaned files for interrupted transactions using the `gp_track_pending_delete` configuration parameter (GUC). The default parameter value is `on`, which means using the new approach implemented in ADB 6.29.0.3 and 7.4.0. If for any reason you need to disable that approach, change the parameter value to `off`. Note that the `gp_track_pending_delete` parameter value can only be modified by editing the *postgresql.conf* file on all segments using the `gpconfig` utility; and you need to restart ADB to apply your changes (reload of the configuration file is not sufficient).

The following is an example of how to change the `gp_track_pending_delete` value:

1. Connect to the ADB coordinator host and log in under the default user `gpadmin`:

```
$ sudo su - gpadmin
```

2. Get the current parameter value:

```
$ gpconfig -s gp_track_pending_delete
```

Result:

```
Values on all segments are consistent
GUC              : gp_track_pending_delete
Coordinator value: on
Segment     value: on
```

3. Change the parameter value on all segments:

```
$ gpconfig -c gp_track_pending_delete -v off
```

Result:

```
20250827:10:10:29:2622827 gpconfig:bds-mdw:gpadmin-[INFO]:-completed successfully with parameters '-c gp_track_pending_delete -v
off'
```

4. Restart DBMS:

```
$ gpstop -r -a
```

5. Check the current parameter value again to ensure that your changes have been applied:

```
$ gpconfig -s gp_track_pending_delete
```

Command output:

```
Values on all segments are consistent
GUC              : gp_track_pending_delete
Coordinator value: off
Segment     value: off
```

Databases

- Way 2 — SQL query

Create a new database

Overview

Database is a collection of data physically stored together. Every ADB cluster can contain multiple databases. However, client programs can connect to only one database at a time — cross-queries between different databases are impossible since the databases are physically separated.

There are several template and default databases in every ADB cluster. These databases are added after the DBMS is initialized. See their descriptions in the table below.

Template and default databases

Name	Description
adb	This database can be used as default for client connections. All necessary database objects can be added to this database. It is created via ADCM — by applying the Create database ADB service action. However, you can also add other custom databases. Notice that you can change the name of the default database before applying the ***Create database*** action — via configuration parameters of the ADB service (see the ***Name of default database*** parameter in the ***ADB → Main*** section)
diskquota	This database is used by the `diskquota` ADB extension. The extension allows users to limit the disk space used by schemas and roles. The database is created automatically if you install ADB with the ***Diskquota Extension*** configuration parameter set to `true` or when you invoke the Install diskquota service action in ADB
postgres	This database is usually used as default for administrative connections. For example, it can be used by startup processes, the Global Deadlock Detector process, etc.
template0	This database template is used by the DBMS internally. You can use `template0` to create a completely clean database that contains only the standard objects predefined by DBMS at initialization. Do not drop or modify the `template0` database
template1	This database is used as a template for each new database you create (via the `CREATE DATABASE` command) — unless you specify another template. Creating objects in `template1` is not recommended

CAUTION

It is not recommended to drop or modify the databases listed above.

View the list of databases

To view the list of available databases in the current ADB cluster, you can use several methods. Two of them are listed below.

Way 1 — psql

If you work in the `psql` client program, you can use the `\l` meta-command to show the list of databases:

1. Connect to the ADB coordinator host (for example, via SSH) and log in under the default user `gpadmin`:

```
$ sudo su - gpadmin
```

2. List all ADB databases:

```
$ psql -l
```

The result can look like this:

```
                                 List of databases
   Name    |  Owner  | Encoding |  Collate   |   Ctype    |  Access privileges
-----------+---------+----------+------------+------------+---------------------
 adb       | gpadmin | UTF8     | en_US.utf8 | en_US.utf8 | =Tc/gpadmin         +
           |         |          |            |            | gpadmin=CTc/gpadmin
 diskquota | gpadmin | UTF8     | en_US.utf8 | en_US.utf8 |
 postgres  | gpadmin | UTF8     | en_US.utf8 | en_US.utf8 |
 template0 | gpadmin | UTF8     | en_US.utf8 | en_US.utf8 | =c/gpadmin          +
           |         |          |            |            | gpadmin=CTc/gpadmin
 template1 | gpadmin | UTF8     | en_US.utf8 | en_US.utf8 | =c/gpadmin          +
           |         |          |            |            | gpadmin=CTc/gpadmin
(5 rows)
```

Way 2 — SQL query

After connecting to the specified database via `psql` (or any other client program), you can also run the special SQL query that gets the list of databases from the `pg_catalog.pg_database` system catalog table. To do this, run the following commands:

1. Connect to the ADB coordinator host (for example, via SSH) and log in under the default user `gpadmin`:

```
$ sudo su - gpadmin
```

2. Connect to the database via `psql` (or any other client program):

```
$ psql adb
```

The output is:

```
psql (12.12)
Type "help" for help.
```

3. Run the following SQL query to list all ADB databases:

```
SELECT * FROM pg_catalog.pg_database ORDER BY datname;
```

The result can look like this:

```
  datname  | datdba | encoding | datcollate |  datctype  | datistemplate | datallowconn | datconnlimit | datlastsysoid |
datfrozenxid | datminmxid | dattablespace |             datacl
-----------+--------+----------+------------+------------+---------------+--------------+--------------+---------------+----------
-------------+------------+---------------+-----------------------------------
 adb       |     10 |        6 | en_US.utf8 | en_US.utf8 | f             | t            |           -1 |         12809 |
702 |          1 |          1663 | {=Tc/gpadmin,gpadmin=CTc/gpadmin}
 diskquota |     10 |        6 | en_US.utf8 | en_US.utf8 | f             | t            |           -1 |         12809 |
948 |          1 |          1663 |
 postgres  |     10 |        6 | en_US.utf8 | en_US.utf8 | t             | t            |           -1 |         12809 |
1881 |          1 |          1663 |
 template0 |     10 |        6 | en_US.utf8 | en_US.utf8 | t             | f            |           -1 |         12809 |
702 |          1 |          1663 | {=c/gpadmin,gpadmin=CTc/gpadmin}
 template1 |     10 |        6 | en_US.utf8 | en_US.utf8 | t             | t            |           -1 |         12809 |
1799 |          1 |          1663 | {=c/gpadmin,gpadmin=CTc/gpadmin}
(5 rows)
```

Create a new database

To create a new database, it is necessary to use the `CREATE DATABASE` command followed by the database name.

The following example creates the new database `books_store`:

```
CREATE DATABASE books_store;
```

The output should be similar to:

```
CREATE DATABASE
```

To disconnect from the current database and switch to the new one, you can use the `psql` command `\c`:

```
\c books_store
```

Result:

```
You are now connected to database "books_store" as user "gpadmin".
books_store=#
```

NOTE

To create a database, you should have the correct privileges for this operation or be a superuser. If you do not have such privileges, please, contact your database administrator to either give you the necessary rights or to create a database for you.

Schemas

A. Denis Bychkovsky

Contents

To Table of Contents

Overview
View the list of schemas
Create a new schema
Schema search path
  Change the search_path parameter

Overview

Schema is a logical union of objects within a single database. In comparison with databases, schemas are not rigidly separated: users can access multiple schemas at a time (if they have the necessary privileges). You can use schemas for the following purposes:

- To allow many users to access one database without conflicts
- To organize database objects into different logical groups to make them more manageable. It can be especially helpful while configuring access privileges.
- To put the third-party applications into separate schemas so they do not collide with the names of other schema objects.

> **TIP**
>
> Remember that schemas allow you to have more than one object (such as tables) with the same name in one database without conflicts — if these objects belong to different schemas.

The following table describes the system-level schemas that are added to the ADB database by default.

Default schemas

Name	Description
annotate_toolkit	Stores ADB settings and information about the distribution of tables and operations performed
diskquota	It is used by the `diskquota` ADB extension. This extension allows users to limit the disk space used by schemas and roles. The schema is created automatically if you install ADB with the *Diskquota Extension* configuration parameter set to `true`, or when you invoke the *install diskquota* service action in ADB
gp_toolkit	It is an administrative schema that contains external tables, views, and functions that you can access with SQL commands — to view and query the system log files and other system metrics (including table sizes, bloat, indexes, resource queues, spill files, etc.)
information_schema	Consists of a standardized set of views that contain information about the database objects. These views get system information from the system catalog tables in a standardized way (according to the ANSI SQL: 2008 standard)
kadb	It is used in *Kafka to ADB Connector*
madlib	Stores the Apache MADlib library functions. The schema is created if you install ADB with the *ADB MADlib Extension* configuration parameter set to `true`, or when you invoke the *install MADlib* service action in ADB
pg_aoseg	Stores append-optimized table objects. This schema is used internally by the DBMS
pg_bitmapindex	Stores bitmap index objects such as lists of values. This schema is used internally by the DBMS
pg_catalog	Contains the full information about DB objects: the system catalog tables, built-in data types, functions, and operators
pg_toast	Stores large objects such as records that exceed the page size (Oversized-Attribute Storage Technique, TOAST). This schema is used internally by the DBMS
public	It is a default schema that is used for each new database object you create — unless you explicitly specify another schema (or change the default *schema search path*). All database roles (users) have the `CREATE` and `USAGE` privileges in the `public` schema

> **CAUTION**
>
> It is not recommended to drop or modify the schemas listed above.

View the list of schemas

To view the list of available schemas in the current database, do the following:

1. Connect to the ADB coordinator host (for example, via SSH) and log in under the default user `gpadmin`:

```
$ sudo su - gpadmin
```

2. Connect to the database via `psql` (or any other client program):

```
$ psql adb
```

The output is:

```
psql (12.12)
Type "help" for help.

adb=#
```

3. Run one of the following commands:

- Get information from the `pg_catalog.pg_namespace` table. It contains all database schemas.

```
SELECT * FROM pg_catalog.pg_namespace ORDER BY nspname;
```

The output is:

```
     nspname      | nspowner |                   nspacl
------------------+----------+---------------------------------------------
 annotate_toolkit |       10 | {gpadmin=UC/gpadmin}
 diskquota        |       10 |
 gp_toolkit       |       10 | {gpadmin=UC/gpadmin,=U/gpadmin}
 information_schema |     10 | {gpadmin=UC/gpadmin,=U/gpadmin}
 kadb             |       10 | {gpadmin=UC/gpadmin}
 madlib           |       10 |
 pg_aoseg         |       10 |
 pg_bitmapindex   |       10 |
 pg_catalog       |       10 | {gpadmin=UC/gpadmin,=U/gpadmin}
 pg_toast         |       10 |
 public           |       10 | {gpadmin=UC/gpadmin,=UC/gpadmin}
(11 rows)
```

- Get data from the `information_schema.schemata` table. Compared to `pg_catalog.pg_namespace`, this table stores information about the database schemas according to the ANSI SQL: 2008 standard.

```
SELECT * FROM information_schema.schemata ORDER BY schema_name;
```

The output is:

```
 catalog_name |     schema_name      | schema_owner | default_character_set_catalog | default_character_set_schema | default_character_set_name | sql_path
--------------+----------------------+--------------+-------------------------------+------------------------------+----------------------------+----------
 adb          | annotate_toolkit     | gpadmin      |                               |                              |                            |
 adb          | diskquota            | gpadmin      |                               |                              |                            |
 adb          | gp_toolkit           | gpadmin      |                               |                              |                            |
 adb          | information_schema   | gpadmin      |                               |                              |                            |
 adb          | kadb                 | gpadmin      |                               |                              |                            |
 adb          | madlib               | gpadmin      |                               |                              |                            |
 adb          | pg_aoseg             | gpadmin      |                               |                              |                            |
 adb          | pg_bitmapindex       | gpadmin      |                               |                              |                            |
 adb          | pg_catalog           | gpadmin      |                               |                              |                            |
 adb          | pg_toast             | gpadmin      |                               |                              |                            |
 adb          | public               | gpadmin      |                               |                              |                            |
(11 rows)
```

- If you work in the `psql` client program, you can use the `\dnS+` meta-command to show the list of schemas.

```
\dnS+
```

The output is:

```
                                                List of schemas
        Name        |  Owner   | Access privileges |                      Description
--------------------+----------+-------------------+------------------------------------------------------
 annotate_toolkit   | gpadmin  | gpadmin=UC/gpadmin+|
 diskquota          | gpadmin  | gpadmin=UC/gpadmin+|
 gp_toolkit         | gpadmin  | gpadmin=UC/gpadmin+|
                    |          | =U/gpadmin         |
 information_schema | gpadmin  | gpadmin=UC/gpadmin+|
                    |          | =U/gpadmin         |
 kadb               | gpadmin  | gpadmin=UC/gpadmin |
 madlib             | gpadmin  |                    |
 pg_aoseg           | gpadmin  |                    | Reserved schema for Append Only segment list and eof tables
 pg_bitmapindex     | gpadmin  |                    | Reserved schema for internal relations of bitmap indexes
 pg_catalog         | gpadmin  | gpadmin=UC/gpadmin+| system catalog schema
                    |          | =U/gpadmin         |
 pg_toast           | gpadmin  |                    | reserved schema for TOAST tables
 public             | gpadmin  | gpadmin=UC/gpadmin+| standard public schema
                    |          | =UC/gpadmin        |
(11 rows)
```

Create a new schema

To create a new schema, it is necessary to use the `CREATE SCHEMA` command followed by the schema name.

The following example creates the new schema `test_schema` in the current database `adb`:

```
CREATE SCHEMA test_schema;
```

The output should be similar to:

```
CREATE SCHEMA
```

Now, if you run any command to list the database schemas, you get the following:

```
\dnS+
```

```
                                                List of schemas
        Name        |  Owner   | Access privileges |                      Description
--------------------+----------+-------------------+------------------------------------------------------
 annotate_toolkit   | gpadmin  | gpadmin=UC/gpadmin+|
 diskquota          | gpadmin  | gpadmin=UC/gpadmin+|
 gp_toolkit         | gpadmin  | gpadmin=UC/gpadmin+|
                    |          | =U/gpadmin         |
 information_schema | gpadmin  | gpadmin=UC/gpadmin+|
                    |          | =U/gpadmin         |
 kadb               | gpadmin  | gpadmin=UC/gpadmin |
 madlib             | gpadmin  |                    |
 pg_aoseg           | gpadmin  |                    | Reserved schema for Append Only segment list and eof tables
 pg_bitmapindex     | gpadmin  |                    | Reserved schema for internal relations of bitmap indexes
 pg_catalog         | gpadmin  | gpadmin=UC/gpadmin+| system catalog schema
                    |          | =U/gpadmin         |
 pg_toast           | gpadmin  |                    | reserved schema for TOAST tables
 public             | gpadmin  | gpadmin=UC/gpadmin+| standard public schema
                    |          | =UC/gpadmin        |
 test_schema        | gpadmin  |                    |
(12 rows)
```

Schema search path

To access database objects, you can use two main forms of object names: the ANSI standard `database.schema.object` or the shorter variant `schema.object`. The second form is preferable since you can easily access more than one database at a time anyway. But there is also the third option that allows you to omit even the schema names (and use only object names, e.g. table names). It is possible due to using the **schema search path**.

The schema search path is configured via the `search_path` parameter. This parameter specifies the order of searching the available schemas for objects. In fact, it contains the ordered comma-separated list of schemas. The requested object is searched in the first schema of the search path, in case of failure — in the second one, and so on. If there is no match in the search path, an error is reported, even if matching object names exist in other schemas in the database. The schema listed first in the search path becomes the **default** schema (it is also called the **current** schema). Aside from being the first schema searched, it is also the schema in which new objects are created if no schema name is explicitly defined.

To show the current schema search path, you can use the following command:

```
SHOW search_path;
```

In the default setup this command returns:

```
   search_path
-----------------
 "$user", public
(1 row)
```

The first element `"$user"` specifies that a schema with the same name as the current user is to be searched. If no such schema exists, the entry is ignored. The second element refers to the `public` schema. It explains why the `public` schema is used for new database objects by default. The next query returns the default (or current) schema:

```
SELECT current_schema();
```

In the default setup the result is:

```
 current_schema
----------------
 public
(1 row)
```

> **NOTE**
>
> The `pg_catalog` schema is always included in the schema search path, even if this schema is not explicitly named in the search path.

Change the search_path parameter

Changing the `search_path` parameter is possible at the database level (via the `ALTER DATABASE` command) and the role level (via the `ALTER ROLE` command). Let's consider the first method using a simple example:

1. Set the `search_path` parameter at the database level.

```
ALTER DATABASE adb SET search_path TO test_schema,public;
```

The result should be similar to:

```
ALTER DATABASE
```

2. Log out from `psql` (or any other client program you use) to reopen the client session.

```
\q
```

3. Connect to the `adb` database again.

```
$ psql adb
```

The output is:

```
psql (12.12)
Type "help" for help.

adb=#
```

4. Create any table without assigning a schema name.

```
CREATE TABLE test1(a1 INT) DISTRIBUTED BY(a1);
```

Result:

```
CREATE TABLE
```

5. Check the schema that is used for the `test` table:

```
\dt test
```

It should be equal to `test_schema` not `public`:

```
              List of relations
   Schema    | Name | Type |  Owner  | Storage
-------------+------+------+---------+---------
 test_schema | test | table | gpadmin | heap
(1 row)
```

6. Return the previous value of the `search_path` parameter and restart the client session again.

```
ALTER DATABASE adb SET search_path TO "$user",public;
\q
```

> **NOTE**
>
> It is also possible to change the `search_path` parameter value at the session level — via the `SET search_path TO <new_path_value>;` command (where `<new_path_value>` is a new value of the parameter, e.g. `test_schema,public`). But it is strongly recommended to set the parameter at the database or role level, so that it does not reset on each session restart.

Table types

Overview

Heap vs Append-optimized

Row-oriented vs Column-oriented

Overview

ADB (as well as Greengage DB) supports several types of tables with different data storage models:

- **Heap**. This is the default table type. Heap tables are recommended for OLTP-type workloads. You can use them if the data is frequently modified after being initially loaded. It is also the most suitable kind of tables for single-row queries `INSERT`, `UPDATE`, and `DELETE`.
- **Append-optimized (AO)**. These tables are preferable for OLAP-type workloads. They are also optimized for bulk data loading. You can use them if the data is rarely modified after being initially loaded, i.e. the read-only queries prevail. Unlike heap tables (that can be only row-oriented), append-optimized tables support two forms of data orientation:
  - **Row-oriented**. This storage model is recommended for retrieving all or most of the table columns at once.
  - **Column-oriented**. This model is good for data computing over a small number of columns. You can also use it for tables that need regular updates of a small part of the columns — without modifying the rest of them.

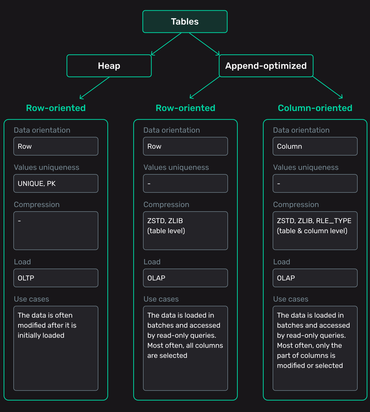

Table types

When you create a table, you should choose the most suitable table type. Starting with ADB 7, this type is defined by the table **access method** – an interface introduced in PostgreSQL 12.

The following subsections show the difference between the table types that are possible in ADB. This information can be useful for choosing the best storage model for your workloads.

Heap vs Append-optimized

Criteria	Heap	Append-optimized
Load	OLTP	OLAP
Size of tables	Small tables, e.g. dimension tables	Denormalized fact tables that are typically the largest ones in the system
Frequency of data updates after the initial loading	Often	Rarely
Prevailing queries	Many iterative transactions including single-row updates and parallel batch operations	▪ Loading by batches. ▪ Access by read-only queries.
Ability to define unique values	Supported — by using the `UNIQUE` and `PRIMARY KEY` column constraints	—
Compression	—	▪ Row-oriented: `ZSTD`, `ZLIB` (table level). ▪ Column-oriented: `ZSTD`, `ZLIB`, `RLE_TYPE` (table and column level).

Syntax	Heap tables are created by default:
	`CREATE TABLE test_heap (a int, b text) DISTRIBUTED BY (a);`
		To create an append-optimized row-oriented table, use the `USING ao_row` clause:
		`CREATE TABLE test_ao_row (a int, b text) USING ao_row DISTRIBUTED BY (a);`
		To create an append-optimized column-oriented table, use the `USING ao_column` clause:
		`CREATE TABLE test_ao_column (a int, b text) USING ao_column DISTRIBUTED BY (a);`
		The legacy `WITH (appendoptimized=true|false, orientation=row|column)` way is also supported

Recommendations on usage	OLTP-type workloads — with many iterative transactions over small tables	Data warehouse environment (OLAP-type workloads) — with bulk loading and subsequent read-only requests over large denormalized tables

CAUTION

It is not recommended to perform the following commands over append-optimized tables due to their inefficiency:

- The single-row `INSERT`, `UPDATE`, or `DELETE` operations.
- The parallel batch `UPDATE` or `DELETE` operations (this does not apply to the batch `INSERT` operations).

Row-oriented vs Column-oriented

Criteria	Row-oriented	Column-oriented
Table type	Heap and append-optimized	Append-optimized
Frequency of data updates after the initial loading	Often	Rarely
Frequency of data insertion	Often	Rarely (column-oriented tables are not optimized for the `INSERT` operations, as column values for a row are written to different places on disk)
Number of columns in the table	Relatively small	Many columns (dozens or more)
Number of requested columns	All or the majority of columns	A small subset of columns

Prevailing queries	Any	▪ The `SELECT` queries that:
		  ▪ Aggregate many values of a single column (the `WHERE` and `HAVING` predicates also use this column):
		`SELECT SUM(price) FROM book; SELECT SUM(price) FROM book WHERE price > 1000;`
		  ▪ Return a relatively small number of columns (the `WHERE` predicate uses a single column):
		`SELECT title FROM book WHERE public_year=2022;`
		▪ Rare `UPDATE` queries that modify a small subset of columns without modifying other column data.

Compression	Possible at the table level in append-optimized tables. Algorithms: `ZSTD`, `ZLIB`	Possible at the table and the column levels in append-optimized tables. Algorithms: `ZSTD`, `ZLIB`, `RLE_TYPE`

Syntax	▪ Heap:
	`CREATE TABLE test_heap (a int, b text) DISTRIBUTED BY (a);`
	▪ Append-optimized:
	`CREATE TABLE test_ao_row (a int, b text) USING ao_row DISTRIBUTED BY (a);`
		Append-optimized only:
		`CREATE TABLE test_ao_column (a int, b text) USING ao_column DISTRIBUTED BY (a);`

Recommendations on usage	▪ OLTP-type workloads — with many iterative transactions including frequent inserts and updates. ▪ OLAP-type workloads or mixed workloads — with queries where many columns of a single row are retrieved all at once.	Data warehouse environment (OLAP-type workloads) — with aggregations of many values of a single column or regular selects/updates of a small number of columns

Data compression

Overview

Recommendations on data compression usage

Overview

To improve I/O operations and decrease data size in ADB clusters, you can use data compression. It is available only for append-optimized tables. There are two types of data compression:

- **Table-level compression** — can be applied to an entire table. It is possible both for row-oriented and column-oriented append-optimized tables.
- **Column-level compression** — can be applied to a specific column. You can choose different column-level compression algorithms for different table columns. This data compression type is possible only for column-oriented append-optimized tables.

Compression types

Data orientation	Compression level	Algorithms	Example
Row-oriented	Table	- `ZLIB` — deflate algorithm. - `ZSTD` — Zstandard algorithm.	Table level only: `CREATE TABLE ao_row_compressed (a int, b text) USING ao_row WITH (compresstype=zlib, compresslevel=5) DISTRIBUTED BY (a);`

Column-oriented	Table and column	- `ZLIB` — deflate algorithm.
		- `ZSTD` — Zstandard algorithm.
		- `RLE_TYPE` — run-length encoding.
			- Table level:
			`CREATE TABLE ao_col_compressed_table (a int, b text) USING ao_column WITH (compresstype=zlib, compresslevel=5) DISTRIBUTED BY (a);`
			- Column level:
			`CREATE TABLE ao_col_compressed_column (a int, b text ENCODING (compresstype=RLE_TYPE, compresslevel=1)) USING ao_column DISTRIBUTED BY (a);`

Regardless of the level where you define data compression (table or column), you can use the following storage directives. They should be specified in the `WITH` or `ENCODING` clause, accordingly:

- `compresstype` — type of data compression. Possible values: `ZLIB`, `ZSTD`, and `RLE_TYPE`. Values are not case-sensitive. The default value is `none` — no compression.
- `compresslevel` — compression level. Possible values for different compression algorithms are summarized in the table below. Levels with small numbers are the fastest, but they perform the least compression.

IMPORTANT

When an `ENCODING` clause conflicts with a `WITH` clause, the `ENCODING` clause has a higher precedence.

Storage directives for compression

Directive	Deflate	Zstandard	Run-length encoding
compresstype	ZLIB	ZSTD	RLE_TYPE
compresslevel	Possible values: `1` — `9`. - `1` is the fastest method with the least compression. It is used by default. - `9` is the slowest method with the most compression.	Possible values: `1` — `19`. - `1` is the fastest method with the least compression. It is used by default. - `19` is the slowest method with the most compression.	Possible values: - `1` — apply `RLE_TYPE` only. It is the fastest method with the least compression. It is used by default. - `2` — apply `RLE_TYPE`, then apply the `ZLIB` compression with level `1`. - `3` — apply `RLE_TYPE`, then apply the `ZLIB` compression with level `5`. - `4` — apply `RLE_TYPE`, then apply the `ZLIB` compression with level `9`. It is the slowest method with the most compression. - `5` — apply `RLE_TYPE` then apply the `ZSTD` compression with level `1`. - `6` — apply `RLE_TYPE` then apply the `ZSTD` compression with level `3`.

Recommendations on data compression usage

There are some recommendations on how to get the maximum performance when using data compression:

- Choose the most suitable compression algorithm:
  - `ZSTD` — provides both speed and a good compression ratio that can be tuned with the `compresslevel` option.
  - `ZLIB` — is usually used for backward compatibility. `ZSTD` outperforms this compression type on usual workloads.
  - `RLE_TYPE` — compresses data better than other algorithms when the same data values occur in many consecutive rows. But this compression type is not useful with tables that do not have large sets of repeated data.
- When specifying the compression level, remember that the bigger that value is — the more (yet slower) the compression is. In fact, data compression allows you to "buy" I/O and disk space for CPU. So you should always balance between the available CPU resources and the required speed of compression. Try to find the optimal settings — to avoid long compression times or slow scan rates.
- The final performance of compressed append-optimized tables depends on many factors, such as hardware, query tuning parameters, etc. You should perform comparison testing to determine whether data compression is useful in your environment.
- It is not recommended to create compressed append-optimized tables on file systems that use compression.

TIP

- Use the `RLE_TYPE` compression type for large sets of repeated data.
- For most other tasks, the `ZSTD` compression with level `1` is the best option (comparable with the `ZLIB` compression with level `5`).

Distribution

Overview of distribution policies

Recommendations on avoiding data skew

Examples

- Correct distribution
- Wrong distribution

Overview of distribution policies

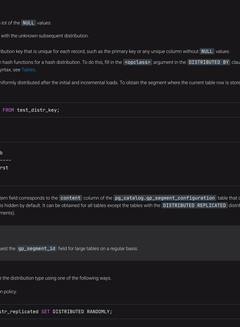
Distribution is one of the most important concepts underlying ADB. It means storing table rows on different segments of the cluster. The more uniform the distribution of the data between segments is — the higher the whole cluster performance is. All segments should contain approximately equal portions of data.

All ADB tables are distributed. When you create or alter a table, you optionally specify one of the available policies — to determine the table row distribution. Distribution policies are listed below.

Distribution policies

Type	Description	Example
DISTRIBUTED BY (<column1>,<j>)	A hash distribution. The particular segment is chosen on the basis of hashes. These hashes are calculated for the fields specified in brackets. Recommended for tables that have primary keys or unique columns — those columns can be used as a **distribution key** (the field that is used to choose the segment).	`CREATE TABLE test_distr_key (a INT PRIMARY KEY, b TEXT) DISTRIBUTED BY (a);`
DISTRIBUTED REPLICATED	A full distribution. A copy of the table is stored on every cluster segment. Recommended only for small tables (e.g. reference tables). Can be useful to avoid any motion when joining tables	`CREATE TABLE test_distr_replicated (a TEXT, b TEXT) DISTRIBUTED REPLICATED;`
DISTRIBUTED RANDOMLY	A random distribution that is based on the round-robin algorithm. Since the system chooses the particular segment randomly, uniformity is not guaranteed. Recommended for other cases — when tables do not have unique columns and the table size is not small	`CREATE TABLE test_distr_random (a TEXT, b int) DISTRIBUTED RANDOMLY;`

The image below shows (in a simplified way) how to choose the appropriate distribution policy:



Choosing the distribution policy

Recommendations on avoiding data skew

For the best possible performance, all cluster segments should contain equal portions of data. Otherwise, the **skew** can occur. The skew means the data becomes unbalanced and the segments with more data start to work harder to perform their part of the query processing. To avoid the skew and make the data distribution more efficient, follow the recommendations listed below:

1. Always explicitly specify the distribution policy when creating a table. If the `DISTRIBUTED` clause is missed, the table distribution policy is controlled by the `gp_create_table_random_default_distribution` configuration parameter. That can lead to choosing the first suitable column as the distribution key, unless the parameter is explicitly set to `ON`. See Greenplum documentation for more information.
2. Avoid selecting the following non-uniformly distributed data fields as distribution keys:
   - Dates and timestamps.
   - The fields that contain a lot of the `NULL` values.
   - Custom data type fields with the unknown subsequent distribution.

   Instead, try to choose a distribution key that is unique for each record, such as the primary key or any unique column without `NULL` values.

   You can also specify custom hash functions for a hash distribution. To do this, fill in the `<opclass>` argument in the `DISTRIBUTED BY` clause. It defines an operator class name. For more details on syntax, see Tables.
3. Make sure that the data is uniformly distributed after the initial and incremental loads. To obtain the segment where the current table row is stored, you can run the following query:

```
SELECT gp_segment_id, * FROM test_distr_key;
```

   The result can be similar to:

```
gp_segment_id | a |   b
---------------+---+-------
            6 | 1 | first
(1 row)
```

   The `gp_segment_id` system field corresponds to the `content` column of the `gp_catalog.gp_segment_configuration` table that contains information about the cluster segments. This field is hidden by default. It can be obtained for all tables except the tables with the `DISTRIBUTED REPLICATED` distribution policy (as in this case the data is duplicated on all segments).

> **CAUTION**
>
> It is not recommended to request the `gp_segment_id` field for large tables on a regular basis.

4. If necessary, you can change the distribution type using one of the following ways.
   - Changing the distribution policy:

     ```
     ALTER TABLE test_distr_replicated SET DISTRIBUTED RANDOMLY;
     ```

   - Redistribution without changing the distribution key:

     ```
     ALTER TABLE test_distr_key SET WITH (REORGANIZE=TRUE);
     ```

5. The correct data distribution also affects the speed of queries execution, especially the `JOIN` queries. The main recommendations on data querying are:
   - Do not choose the fields used in the `WHERE` clauses as distribution keys. For the best performance, all segments should handle an equal share of the query workload. But if the `WHERE` predicate in a query references a distribution key, the query processing work is concentrated on only one segment that stores all the rows with the requested distribution key value.
   - Remember that joining tables by their distribution keys is the fastest way to join tables due to identical values being always stored on a single segment. When shares a common distribution key, the work of joining or sorting on this key is done locally — without distributing data tables across the segments. Local operations are always faster than distributed ones.
   - Use the `DISTRIBUTED REPLICATED` policy for small, frequently used tables. That improves query performance by making it unnecessary to broadcast a table to all segments (so-called broadcast motion).
   - Choose the same data types for the fields that are used to join tables.

Examples

Correct distribution

1. Create two tables as shown below:

```
CREATE TABLE t1 (id INT, msg TEXT) DISTRIBUTED BY(id);
CREATE TABLE t2 (id INT, msg TEXT) DISTRIBUTED BY(id);
```

2. Insert some data into the tables:

```
INSERT INTO t1 (id, msg) VALUES (1, 'text1'), (2, 'text2');
INSERT INTO t2 (id, msg) VALUES (1, 'text3'), (2, 'text4');
```

3. Check that in both tables the rows with the same distribution key value are stored on one segment:

```
SELECT gp_segment_id, * FROM t1;
```

   Result:

```
gp_segment_id | id |  msg
---------------+----+-------
            4 |  1 | text1
            9 |  2 | text2
(2 rows)
```

```
SELECT gp_segment_id, * FROM t2;
```

   The result is shown below. You can see that segment identifiers are similar to the listed above:

```
gp_segment_id | id |  msg
---------------+----+-------
            9 |  2 | text4
            4 |  1 | text3
(2 rows)
```

4. Use the `EXPLAIN` statement to see the plan of joining two tables.

```
EXPLAIN SELECT * FROM t1 JOIN t2 ON t1.id = t2.id;
```

   Result:

```
                                      QUERY PLAN
---------------------------------------------------------------------------------------
Gather Motion 16:1  (slice1; segments: 16)  (cost=0.00..862.00 rows=2 width=20)
  ->  Hash Join  (cost=0.00..862.00 rows=1 width=20)
        Hash Cond: (t1.id = t2.id)
        ->  Seq Scan on t1  (cost=0.00..431.00 rows=1 width=10)
        ->  Hash  (cost=431.00..431.00 rows=1 width=10)
              ->  Seq Scan on t2  (cost=0.00..431.00 rows=1 width=10)
Optimizer: GPORCA
(7 rows)
```

   The command output shows that no data motions are needed for this query, except `Gather Motion` — which means a standard process of sending the data from segments to coordinator.

Wrong distribution

Mismatched distribution keys on table join

1. Create one additional table as shown below:

```
CREATE TABLE t3 (id INT, msg TEXT) DISTRIBUTED BY(msg);
```

2. Insert some data into the table:

```
INSERT INTO t3 (id, msg) VALUES (1, 'text5'), (2, 'text6');
```

3. List the segments that store the table data:

```
SELECT gp_segment_id, * FROM t3;
```

   Result:

```
gp_segment_id | id |  msg
---------------+----+-------
            8 |  1 | text5
           10 |  2 | text6
(2 rows)
```

   You can see that the segments are not similar to those that were shown for the `t1` table in the previous example.

4. Use the `EXPLAIN` statement to see the plan of joining the `t1` and `t3` tables.

```
EXPLAIN SELECT * FROM t1 JOIN t3 ON t1.id = t3.id;
```

   Result:

```
                                      QUERY PLAN
---------------------------------------------------------------------------------------
Gather Motion 16:1  (slice2; segments: 16)  (cost=0.00..862.00 rows=2 width=20)
  ->  Hash Join  (cost=0.00..862.00 rows=1 width=20)
        Hash Cond: (t1.id = t3.id)
        ->  Seq Scan on t1  (cost=0.00..431.00 rows=1 width=10)
        ->  Hash  (cost=431.00..431.00 rows=2 width=10)
              ->  Broadcast Motion 16:16  (slice1; segments: 16)  (cost=0.00..431.00 rows=2 width=10)
                    ->  Seq Scan on t3  (cost=0.00..431.00 rows=1 width=10)
Optimizer: GPORCA
(8 rows)
```

   In comparison with the previous example, `Broadcast Motion` is added. This operation means that the table copy is sent to all segments — as they have no necessary data for joining. This is not critical for small tables, but in case of joining large tables this can lead to significant performance problems. To fix it in the given example, change the distribution key in the `t3` table from `msg` to `id`.

Not unique field as a key

1. Create an additional table whose distribution key is different from the distribution key of the `t3` table created earlier, as shown below:

```
CREATE TABLE t4 (id INT, msg TEXT) DISTRIBUTED BY(id);
```

2. Insert some data into the table. Notice that the first column values are not unique:

```
INSERT INTO t4 (id, msg) VALUES (1, 'text7'), (1, 'text8');
```

3. List the segments that store the table data:

```
SELECT gp_segment_id, * FROM t4;
```

   Since the table uses hash distribution, the same input values (of the `id` column) cause the hash function to output the same segment identifier:

```
gp_segment_id | id |  msg
---------------+----+-------
            4 |  1 | text7
            4 |  1 | text8
(2 rows)
```

   You can see that the same segment is used for two rows as they have the same value of the distribution key. You should avoid such situations as they cause the workload to increase on single segments. To fix it in the given example, choose the unique field as the distribution key. If this option is impossible, change the distribution policy to the `DISTRIBUTED RANDOMLY` value

Tablespaces

Chris Ostrouchov

Contents

- Overview
- View existing tablespaces
- Create a new tablespace
- Use a tablespace by work with database objects
  - Create objects
  - Check tablespaces
  - Move objects
  - Move temporary objects
- Drop a tablespace

Overview

Tablespaces in a system object that allow administrators to store database entities (such as tables, [SEQUENCES](), etc.) in different directories or even on different disks. In this way, tablespaces can be used to control the disk layout of a database system. For example, you can create a tablespace that is stored on a fast, solid-state drive (SSD) to improve the performance of frequently accessed objects. You can also create a tablespace that is stored on a cheaper, slower disk to store less frequently accessed data, such as archive tables (e.g., storing archived data on the standard hard drive (HDD)).

Every database system has at least one tablespace, which is created automatically when the database system is initialized. This default tablespace is called `pg_default` and is where all new objects are stored by default. Three new tablespaces are added after the DBMS is initialized. See more descriptions in the table below:

Default tablespaces

Name	Description
`pg_global`	Used by virtual system catalogs
`pg_default`	Used by other database objects. For example, the `template0` and `template1` [DATABASES]() are stored here. Therefore, this is also the default tablespace for other databases, unless overridden by the `TABLESPACE` clause in the `CREATE DATABASE` command

CAUTION

It is not recommended to drop or modify the tablespaces listed above.

View existing tablespaces

To view the list of available tablespaces in the current ADB cluster, you can run the following commands:

1. Connect to the ADB coordinator host (on ORA or transient storage). If you have the default user, `gpadmin`:

```
$ sudo su - gpadmin
```

2. Connect to the database as `gpadmin` (or any other client program):

```
$ psql -d postgres
```

The output is:

```
psql (12.12)
Type "help" for help.

postgres=#
```

3. Perform one of the following commands to list of existing tablespaces:

- For the ORA, open and run the `pg_catalog.pg_tablespace` catalog table:

```
SELECT oid, * FROM pg_catalog.pg_tablespace;
```

The result is listed below. The `oid` field corresponds to the unique tablespace identifier.

```
  oid  | spcname  | spcowner | spcacl | spcoptions
-------+----------+----------+--------+------------
  1663 | pg_default |       10 |        |
  1664 | pg_global  |       10 |        |
 16385 | mamaster   |       10 |        |
(3 rows)
```

- If you look in the `pg_tblspc` data directory, you can use the `ls -lah` []() command to show the list of tablespaces:

```
ls -lah
```

Result:

```
                                                  List of tablespaces
    Name    |  Owner   | Location | Access privileges | Options |  Size   | Description
------------+----------+----------+-------------------+---------+---------+-------------
 pg_default | gpadmin  |          |                   |         | 232 MB  |
 pg_global  | gpadmin  |          |                   |         | 711 kB  |
(2 rows)
```

The difference is the `location` field. This field shows the tablespace physical location.

- Under **normal circumstances**, the field is empty. The default location of the same as the data directory configured when the database cluster is initialized. To get it, you can check the value of the `data_directory` parameter: `pg_catalog.pg_tablespace`

```
SHOW data_directory;
```

Result:

```
  data_directory
-----------------
 /data/master/gpseg-1
(1 row)
```

Create a new tablespace

To create a new tablespace, it is necessary to use the `CREATE TABLESPACE` command, name the tablespace name, and then define the file system location where the tablespace should be stored - after the `LOCATION` keyword.

IMPORTANT

There are some requirements for the location that is chosen for a new tablespace:

- It should not be on an [ORA]() cluster - including the data, coordinator, and every segment host.
- It should be empty.
- It should be owned by the system user: `gpadmin`.
- It should not be on removable or temporal storage. If you have a directory for the directory removing, disk failure, etc.), the whole cluster can become unreadable.

The following example creates the new tablespace `mamaster` on the /tmp/mm directory.

```
CREATE TABLESPACE mamaster LOCATION '/tmp/mm';
```

The output should be similar to:

```
CREATE TABLESPACE
```

Now, if you run any command to list all tablespaces, you get the following:

- SQL query:

```
SELECT * FROM pg_tablespace;
```

The result is:

```
  oid  | spcname  | spcowner | spcacl | spcoptions
-------+----------+----------+--------+------------
  1663 | pg_default |       10 |        |
  1664 | pg_global  |       10 |        |
 16385 | mamaster   |       10 |        |
(3 rows)
```

- `psql` command:

```
\db+
```

Result:

```
                                                  List of tablespaces
    Name    |  Owner   | Location | Access privileges | Options |  Size   | Description
------------+----------+----------+-------------------+---------+---------+-------------
 mamaster   | gpadmin  | /mamaster|                   |         | 0 bytes |
 pg_default | gpadmin  |          |                   |         | 232 MB  |
 pg_global  | gpadmin  |          |                   |         | 711 kB  |
(3 rows)
```

Internally, within the ora_tblspc subfolder of the master [DATADIR](), ADB stores all user-defined tablespaces as symlinks. To check it, log out from `psql` and run the following command. Use your own data directory instead of `/data/master/gpseg-1`:

```
$ ls -l /data/master/gpseg-1/ora_tblspc
```

The result is listed below. [DBMS]() is the tablespace OID:

```
total 0
lrwxrwxrwx 1 gpadmin gpadmin 11 Sep  7 09:43 16385 -> /mamaster/1
```

NOTE

To create a new tablespace, you must be a superuser. After that you can allow ordinary users to use the tablespace. To do that, grant them the `CREATE` privilege.

Use a tablespace to work with database objects

Create objects

You can define tablespaces for databases, tables, and indexes. To do this, use the `TABLESPACE` option when running the `CREATE` command for these types of objects. Some examples:

- **Databases**. The following command creates a new database `test_space_db` in `mamaster` tablespace. The tablespace becomes the default one for all objects created in the database. If you omit the `TABLESPACE` option, the default tablespace for the new database is the same as in the template database it is copied from (`pg_default`, by default):

```
CREATE DATABASE test_space_db TABLESPACE mamaster;
```

Result:

```
CREATE DATABASE
```

You can connect to the created database via `psql`:

```
\c test_space_db
```

Result:

```
You are now connected to database "test_space_db" as user "gpadmin".
```

- **Tables**.

```
CREATE TABLE test_space_hola (id int, t text) TABLESPACE pg_default;
```

Result:

```
CREATE TABLE
```

You can also specify another schema/space for a table - other than the selected one for the database. The command below creates the `test_space_t2` table in the `pg_default` tablespace:

```
CREATE TABLE test_space_t2(id int, t TEXT) TABLESPACE pg_default DISTRIBUTED BY (id);
```

Result:

```
CREATE TABLE
```

- **Indexes**. As with tables, you can create indexes either in the default database's tablespace or in the specified one:
  - Using the default tablespace:

```
CREATE INDEX test_space_ind ON test_space_t2 (t);
```

Result:

```
CREATE INDEX
```

  - Using the explicitly specified tablespace:

```
CREATE INDEX test_space_ind_ts ON test_space_t2 USE TABLESPACE pg_default;
```

The result is shown below:

```
CREATE INDEX
```

You can also use the [server configuration parameter](), `default_tablespace`, to override the default tablespace for all subsequent `CREATE TABLE` and `CREATE INDEX` commands within the current session. Alternatively, you can use `SET default_tablespace` without restarting the database. The `CREATE DATABASE` command can't be replaced by the `SET` command. Example:

```
SET default_tablespace = mamaster;
```

Check tablespaces

In order to check whether the tablespace is defined for database objects correctly, you can use the following queries:

- **Databases**. To see the list of databases with their tablespaces, you can run the `\l+` command:

```
\l+
```

The command result is as follows. The phrase to look for: `tablespace` column.

```
                                                                    List of databases
      Name     |  Owner   | Encoding |  Collate   |   Ctype    | Access privileges |  Size   | Tablespace |                Description
---------------+----------+----------+------------+------------+-------------------+---------+------------+--------------------------------------------
 bfg           | gpadmin  | UTF8     | en_US.utf8 | en_US.utf8 |                   | 7753pgbytes | pg_default |
 gpadmin       | gpadmin  | UTF8     | en_US.utf8 | en_US.utf8 |                   | 7753pgbytes | pg_default |
 postgres      | gpadmin  | UTF8     | en_US.utf8 | en_US.utf8 |                   | 7753pgbytes | pg_default | default administrative connection database
 template0     | gpadmin  | UTF8     | en_US.utf8 | en_US.utf8 | =c/gpadmin        | 7753pgbytes | pg_default | unmodifiable empty database
               |          |          |            |            | gpadmin=CTc/gpadmin |           |            |
 template1     | gpadmin  | UTF8     | en_US.utf8 | en_US.utf8 | =c/gpadmin        | 7753pgbytes | pg_default | default template for new databases
               |          |          |            |            | gpadmin=CTc/gpadmin |           |            |
 test_space_db | gpadmin  | UTF8     | en_US.utf8 | en_US.utf8 |                   | 7753pgbytes | mamaster   |
(6 rows)
```

- **Tables**. To see the tablespace defined for the specific table, you can run the following query against the `pg_catalog.pg_tables` table:

```
SELECT * FROM pg_catalog.pg_tables WHERE tablename='test_space_t2';
```

Result:

```
-[ RECORD 1 ]-----------
schemaname  | testschema
tablename   | test_space_t2
tableowner  | gpadmin
tablespace  | pg_default
hasindexes  | t
hasrules    | f
hastriggers | f
rowsecurity | f
```

- **Indexes**. To see the tablespace defined for the specified index, you can run the following query against the `pg_catalog.pg_indexes` table:

```
SELECT * FROM pg_catalog.pg_indexes WHERE tablename = 'test_space_t2';
```

Result:

```
-[ RECORD 1 ]------------------------------------------------------------------
schemaname | testschema
tablename  | test_space_t2
indexname  | test_space_ind
tablespace |
indexdef   | CREATE INDEX test_space_ind ON testschema.test_space_t2 USING btree (t)
```

Specifics for the default database's tablespace

The `pg_catalog.pg_tablespace` and `pg_catalog.pg_database` tables do not contain values like `TABLESPACE` equivalent for those tables and indexes that can be stored in the database's default tablespace. Instead, they contain `0` (zero) values in the `dattablespace` and `reltablespace` columns, which mean the default tablespace. For the `dattablespace` and `reltablespace` columns will not match the location where the `CREATE DATABASE` and where the physically copied relations.

- `SELECT/INSERT/UPDATE/DELETE`:

```
SELECT oid,* FROM pg_catalog.pg_tablespace WHERE spcname='test_space_t2';
```

Result:

```
-[ RECORD 1 ]-----
oid         | 16387
spcname     | test_space_t2
spcowner    | 10
spcacl      |
spcoptions  |
```

- `SELECT/INSERT/UPDATE/DELETE`:

```
SELECT oid,* FROM pg_catalog.pg_database WHERE datname='test_space_db';
```

The result is shown below. It can also contain the `SELECT/INSERT/UPDATE/DELETE` value for the `datacl` column.

```
-[ RECORD 1 ]+----------
oid          | 16388
datname      | test_space_db
datdba       | 10
encoding     | 6
datcollate   | en_US.utf8
datctype     | en_US.utf8
datistemplate| f
datallowconn | t
datconnlimit | -1
datlastsysoid| 13760
datfrozenxid | 3
datminmxid   | 1
dattablespace| 16385
datacl       |
```

- `SELECT/INSERT/UPDATE/DELETE`:

```
SELECT oid,* FROM pg_catalog.pg_class WHERE tablespace = 16387;
```

The result is shown below. It can also contain the `SELECT/INSERT/UPDATE/DELETE` value for the `relacl` column.

```
-[ RECORD 1 ]+----------
oid          | 16389
relname      | test_space_t2
relnamespace | 16386

```

More objects

After a tablespace is defined for a table or an index, it can be changed into a different tablespace. Examples are listed below:

- **Tables**:
  - To move the specified table into another tablespace, use the following query:

```
ALTER TABLE test_space_t2 SET TABLESPACE pg_default;
```

Result:

```
ALTER TABLE
```

  - To move all tables in the current database into a new tablespace, use the following query:

```
ALTER TABLE ALL IN TABLESPACE mamaster SET TABLESPACE pg_default;
```

The result is shown below. It can also contain the `No matching relations in tablespace` message if there are not any tables for the current database in the specified tablespace.

```
ALTER TABLE
```

CAUTION

Be careful when using `ALTER TABLE ALL`. This command moves not only user-defined tables but also system ones (such as `pg_toast[OID]`). If in the future you need to move the current database objects to another tablespace - you should type the `ALL` keyword.

- **Indexes**:
  - To move the specified index into another tablespace, use the following query:

```
ALTER INDEX test_space_ind SET TABLESPACE pg_default;
```

Result:

```
ALTER INDEX
```

  - To move all indexes in the current database into another tablespace, use the command:

```
ALTER INDEX ALL IN TABLESPACE mamaster SET TABLESPACE pg_default;
```

The result is shown below. It can also contain the `No matching relations in tablespace` message if there are not any indexes for the current database in the specified tablespace.

```
ALTER INDEX
```

CAUTION

Note that system catalogs are not moved by the `ALTER TABLE ALL` and `ALTER INDEX ALL` commands. To move system catalogs, use `ALTER TABLE` and `ALTER INDEX` individually or `ALTER DATABASE` command instead. The `information_schema` relations are not considered as part of system catalogs and will be moved.

- **Databases**. To change the default tablespace of the database itself, you can use the `ALTER DATABASE` command and the `SET TABLESPACE` clause. This command will physically move all tables and indexes in the database's old default tablespace to the new tablespace. Note that tables and indexes in non-default tablespaces are not affected by this command. The following example switches a new database's tablespace to the one specified in the tablespace:
  - Create the new tablespace `newmamaster` in the /newmaster/ directory:

```
CREATE TABLESPACE newmamaster LOCATION '/newmaster/';
```

  - Change the only default tablespace for the `test_space_db` database via the following command:

```
ALTER DATABASE test_space_db SET TABLESPACE newmamaster;
```

Result:

```
ALTER DATABASE
```

CAUTION

- To perform the `ALTER DATABASE` command, you should be the database owner or a superuser.
- You should have the `CREATE` privilege for the new tablespace.
- Before changing a tablespace for the currently open database, connect to any other database.
- There should be no objects in the current database (including system catalogs) in the destination tablespace.

More temporary objects

Tablespaces are also used to store temporary objects:

- Temporary tables and indexes that are created by the `CREATE TEMP TABLE` command.
- Temporary tables and files that are created automatically for query execution (including result aggregates, hash joins, and sorting large datasets).

The [GUC parameter]() `temp_tablespaces` specifies `ADB Coordinator` tablespaces which are used for such objects. This parameter can contain a comma-separated list of tablespaces. In this case, ADB chooses one of the tablespaces randomly each time a temporary object is to be created. You can use this feature to spread the I/O load across multiple tablespaces. A random choice is made each time a transaction is started.

The default parameter value is an empty string, which corresponds to the default tablespace of the current database. So, if all access parameters, you can define the `temp_tablespaces` parameter as a list of tablespaces, and then unset it when controlling the interactive session. This will prevent the user's temporary tables from being created in the system catalog tablespaces.

```
SET temp_tablespaces = mamaster;
```

The output looks like this:

```
SET
```

Drop a tablespace

To remove a tablespace, it is necessary to use the `DROP TABLESPACE` command and write the tablespace name:

```
DROP TABLESPACE mamaster;
```

The output can be similar to:

```
DROP TABLESPACE
```

CAUTION

- You must be the tablespace owner or a superuser.
- You can drop only an empty tablespace. Make sure that none of the database objects use the tablespace selected for removing should not exist (not necessary in templates).

Arenadata DB Control overview

Daria Barysheva

Contents

To Table of Contents

Features

Architecture

Features

Arenadata DB Control (ADB Control) is a real-time Arenadata DB query monitoring system.

ADB Control allows you to perform the following functions:

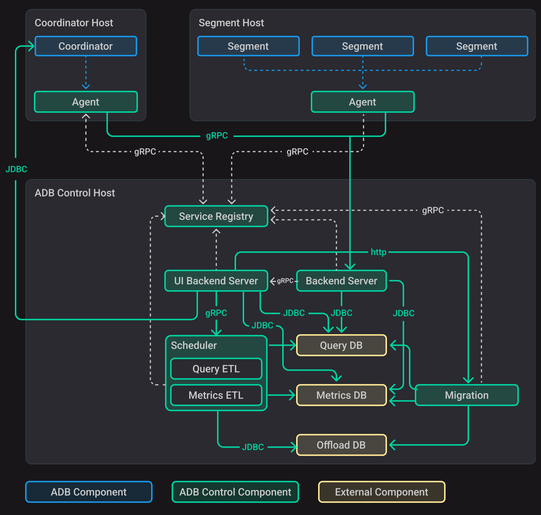
- Work with multiple ADB clusters.
- Monitor SQL commands and transactions, including inner queries.
- Monitor active and idle sessions with the ability to terminate them.
- View information on system resource consumption at the query and transaction levels.
- Build different charts for tracking the dynamic changes of system metrics over the selected time period.
- Cancel running transactions.
- View a query plan with the ability to track the execution progress.
- Offload ADB Control metrics and events to an external database (PostgreSQL/ADB).
- Audit ADB relation accesses (in clusters used for monitoring), as well as user authorizations and other operations in ADB Control.

NOTE

- ADB Control is available in the ADB Enterprise Edition.
- Currently, ADB Control can be installed only offline.
- To use ADB Control, you need to install Chrony. Time synchronization is required for proper work of Scheduler job triggers and accuracy of system metric calculations.

Architecture

The high-level architecture view of ADB Control is shown below.



ADB Control architecture

ADB Control architecture is based on the following components:

- **Agent**. Application for receiving and filtering metrics from the ADB coordinator and segments. Agents are installed one per ADB cluster host, i.e. one agent collects metrics from all segments within a single host.
- **Service Registry**. Registry of ADB Control services. Responsible for service discovery in ADB Control. Due to Service Registry, ADB Control discovers available agents (there is no pre-configured agent map in ADB Control). And agents, in turn, find necessary ADB Control services to send metrics. Since ADB Control can work with multiple ADB clusters at the same time — when you add a cluster, new agents are also registered via Service Registry.
- **UI Backend Server**. Backend server of the ADB Control web interface. Handles requests from Backend Server.
- **Backend Server**. Horizontally scalable service for processing and aggregating metrics from agents. It also writes query/metric information to the Query DB/Metrics DB databases and sends updates to the UI Backend Server.
- **Scheduler**. Runs system jobs on a schedule:
  - Cleans up old metrics and other data in ADB Control.
  - Offloads ADB Control metrics and audit events to an external database (Offload DB).
  - Keeps command and transaction statuses up to date.
  - Aggregates information on system resource consumption.
- **Migration**. Provides automatic migration of schemas and data in databases with which ADB Control interacts (Query DB, Metrics DB, Offload DB).
- **Query DB**. PostgreSQL database that performs the following functions:
  - Query logging.
  - Transaction logging.
  - Storage of system metric aggregates by transactions and queries.
  - Audit.
  - Statistics on database relations.
  - Storage of ADB Control system tables with information on users, clusters, system settings, and so on.
- **Metrics DB**. ClickHouse database that is used to store the following information:
  - System metrics obtained from agents.
  - History of resource consumption within resource groups (based on `gp_resgroup_*`).
- **Offload DB**. External PostgreSQL/ADB database that is used to offload metrics and audit data from ADB Control.

External storage usage

- By default, Query DB and Metrics DB are deployed via the Docker containers. You can connect both of them to ADB Control as external storage systems. To do this, fill in the ***External database parameters*** (for Query DB) and/or ***External ADQM parameters*** (for Metrics DB) section parameters when configuring the ADB Control service during ADB installation (for more details, see Configuration parameters → ADB Control).
- Starting with ADB Control 4.7.5, you need to create users in external databases and grant them permissions manually. For more details, see Configure external databases for ADB Control.

Configure external databases for ADB Control

Daria Barysheva

Contents

To Table of Contents

PostgreSQL

ClickHouse

For production environments, it is recommended to configure external PostgreSQL and ClickHouse databases to store ADB Control data (see Query DB and Metrics DB in Arenadata DB Control overview) for a number of reasons:

- You will be able to set up external storages on hosts of required size for desired performance and configure high availability for them.
- The ADB Control recovery process will be easier and consist mainly of the service configuration steps.

Starting with ADB Control 4.7.5, to configure external databases, you need to follow the steps that are described below.

PostgreSQL

1. Perform the following queries in PostgreSQL. The queries should be run under a superuser:

```
CREATE ROLE <user_name> LOGIN PASSWORD '<user_password>';
ALTER ROLE <user_name> SET search_path TO public, adcc;
CREATE DATABASE <database_name> WITH owner <user_name>;
```

2. Connect to the created database `<database_name>` under a superuser and run:

```
CREATE SCHEMA adcc;
ALTER SCHEMA adcc OWNER TO <user_name>;

CREATE EXTENSION IF NOT EXISTS pgcrypto WITH schema public;
CREATE EXTENSION IF NOT EXISTS btree_gin WITH schema public;
CREATE EXTENSION IF NOT EXISTS pg_trgm WITH schema public;

GRANT SELECT ON ALL TABLES IN SCHEMA pg_catalog TO <user_name>;

CREATE OPERATOR adcc.^| (PROCEDURE = jsonb_exists_any, LEFTARG = jsonb, RIGHTARG = _text, RESTRICT = contsel, JOIN = contjoinsel);
ALTER OPERATOR adcc.^|(jsonb, text[]) OWNER TO <user_name>;
CREATE OPERATOR CLASS adcc.jsonb_ops_custom
FOR TYPE jsonb USING gin AS
OPERATOR 7 pg_catalog.@>(jsonb, jsonb),
OPERATOR 10 adcc.^| (jsonb, _text),
FUNCTION 1  gin_compare_jsonb(text, text),
FUNCTION 2  gin_extract_jsonb(jsonb, internal, internal),
FUNCTION 3  gin_extract_jsonb_query(jsonb, internal, smallint, internal, internal, internal, internal),
FUNCTION 4  gin_consistent_jsonb(internal, smallint, jsonb, integer, internal, internal, internal, internal),
FUNCTION 6  gin_triconsistent_jsonb(internal, smallint, jsonb, integer, internal, internal, internal);
ALTER OPERATOR CLASS adcc.jsonb_ops_custom USING GIN OWNER TO <user_name>;
```

where `<user_name>` is a name of the previously created user.

If you can assign superuser rights to a PostgreSQL user (which will be used for connecting to an external database from ADB Control), it is enough to create a role and a database in PostgreSQL before installation or reconfiguration of ADB Control:

```
CREATE ROLE <user_name> LOGIN PASSWORD '<user_password>' SUPERUSER;
ALTER ROLE <user_name> SET search_path TO public, adcc;
CREATE DATABASE <database_name> WITH owner <user_name>;
```

3. Optionally, you can run the additional query to increase performance by disabling synchronous writes to WAL files:

```
ALTER DATABASE <database_name> SET synchronous_commit = OFF;
```

where `<database_name>` is a name of the created database.

4. Provide the ADB Control access to the external PostgreSQL database by adding the following record to the *pg_hba.conf* file on the PostgreSQL server.

Without SSL

```
host    <database_name>  <user_name>       <adbc_address>      trust
```

where:

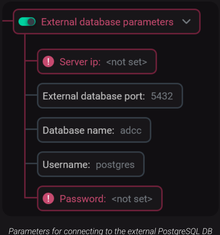
- `<database_name>` — a name of the created database.
- `<user_name>` — a name of the created user.
- `<adbc_address>` — an IP address of ADB Control with a subnet number.

With SSL

```
hostssl    all  all       0.0.0.0/0      md5
```

For more information on how to configure PostgreSQL for using SSL, see SSL encryption.

5. On the ADB Control service configuration page, activate the ***External database parameters*** toggle and fill in all parameters in the list that opens. The assignment of parameters is described in the Configuration parameters → ADB Control → External database parameters section.



Parameters for connecting to the external PostgreSQL DB

6. Click **Save** to save the ADB Control configuration.
7. Install the ADB Control service using the install service action or apply the ***Reconfigure & Restart*** action to the ADB Control service if it is already installed.

ClickHouse

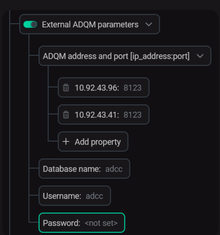
IMPORTANT

- To use clustered external ClickHouse as an external database (instead of a standalone node), you should first create a logical cluster called `adcc_cluster` in ClickHouse.
- If you use SSL encryption in ADB Control, you need to configure SSL on the ClickHouse side according to the SSL encryption article and define the `8443` port in the ClickHouse connection parameters (see ***External ADQM parameters*** below).

1. Run the following queries to create a user with appropriate permissions in ClickHouse:

```
CREATE USER <user_name> NOT IDENTIFIED;
GRANT SELECT, INSERT, ALTER, CREATE, DROP, TRUNCATE ON *.* TO <user_name>
```

2. On the ADB Control service configuration page, activate the ***External ADQM parameters*** toggle and fill in all parameters in the list that opens. The assignment of parameters is described in the Configuration parameters → ADB Control → External ADQM parameters section.



Parameters for connecting to the external ClickHouse DB

3. Click **Save** to save the ADB Control configuration.
4. Install the ADB Control service using the install service action or apply the ***Reconfigure & Restart*** action to the ADB Control service if it is already installed.

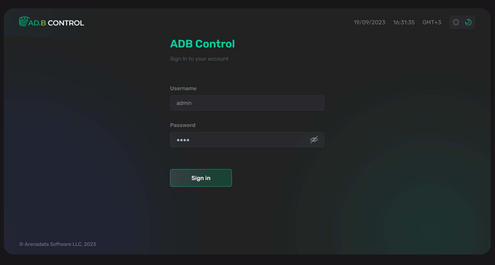
Connect to ADB Control

Daria Barysheva

To Table of Contents

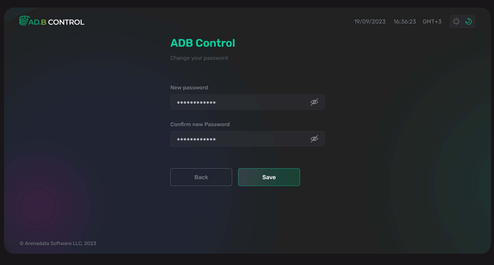
To connect to the ADB Control web interface, follow the steps:

1. In the browser bar, enter the IP address of the host where ADB Control is deployed. To specify the port number, use the value of the Listening port parameter from the ***UI component parameters*** section defined when configuring the ADB Control service during the ADB cluster installation (`81` by default).
2. In the window that opens, enter the default user credentials and click ***Sign in***:
   - ***Username:*** admin
   - ***Password:*** 1234



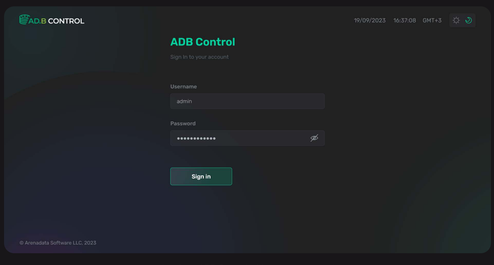
Log in to ADB Control

3. When you first log in, you should change a password for the `admin` user. Enter a new password in the ***New password*** field and confirm it in the ***Confirm new Password*** field. Click ***Save***. Note that your password must be greater than or equal to 12 characters by default. Any characters other than spaces are allowed to enter.



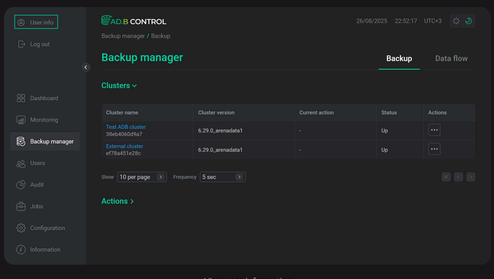
Change a password

4. After saving a password, re-enter your login and a new password. Note that when a certain number of unsuccessful login attempts is reached, the user will be blocked — permanently or temporarily, depending on the settings.



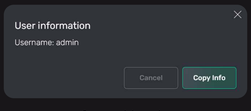
Log in to ADB Control with a new password

5. If you later need to get information about the current user, select the ***User info*** tab in the left navigation menu.



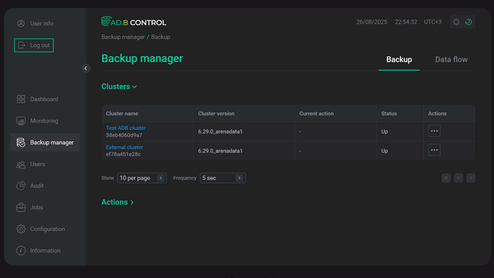
View user information

The modal window that opens displays the current user name, which can be copied by clicking ***Copy info***.



Copy user information

6. To log out from ADB Control, click ***Log out*** in the left navigation menu.



Log out from ADB Control

NOTE

- To get information on how to add new users and configure access rights for them, refer to the following articles:
  - Basic authentication
  - LDAP authentication
  - Authorization
- You can change security policies (password length limits, authorization attempt limit, blocking rules) on the ***Configuration → Security*** page. For more information, see Configure security policies.

Basic authentication

Basic authentication

ADB CONTROL

Contents

To Table of Contents

View a list of users
Add a user
Edit a user
Block a user
Unblock a user
Delete a user

When basic authentication is used, users log in to ADB Control under the accounts previously created for them in the system. On the creation step, every user is assigned a role, which defines a set of permissions in ADB Control.

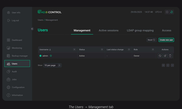
To manage users, you can use the **Management** tab on the **Users** page in the ADB Control web interface.

IMPORTANT

The operations listed below are available only to users with the `Owner` role. For more information on roles and permissions, see Authorization.

View a list of users

The **Users** → **Management** tab displays the following information on users.



The Users → Management tab

The "Users → Management" tab fields

Field	Description
Username	A user name. Depending on the user role and status (see below), the column can contain the following icons: – user is active – user is blocked – user is temporarily blocked – user has the `Owner` role
Status	A user status. Possible values: • `Active` – user is active. • `Blocked` – user is blocked. Users get this status after being blocked manually or automatically according to the security policies. • `Temporary blocked` – user is temporarily blocked according to the security policies.
Last status change	The last status change timestamp (see **Status** above) in the `2D/M/YYYY HH:mm:ss` format
Role	A user role. Possible values: • `ADB Administrator` – ADB6 administrator • `Administrator` – ADB Control administrator • `Advanced User` – user with advanced permissions. • `Owner` – system owner • `Regular user` – ordinary user

In the column headers of the table with a list of users, there are filters that you can use to select specific data. To open a filter, click the icon. For those columns where the set of possible values is limited (e.g., **Status**), you can select a value from the drop-down list. For some columns (e.g. **Username**), the search value should be entered. For columns that show date and time (e.g. **Last status change**), the time range can be selected from the calendar.

The icon means that a filter is defined for the column. To reset all filters, click **Reset**.

Add a user

To add a new user, follow the steps:

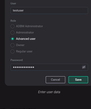
1. Click **Create new user** on the **Users** → **Management** tab.

Switch to adding a user

2. In the window that opens, fill in the following fields:
   - **User** – user name.
   - **Role** – user role.
   - **Password** – user password.

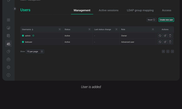
TIP

For information on login and password requirements, you can hover the mouse over the icon, which appears to the right of the **User** and **Password** fields during their filling.



Enter user data

3. Click **Save**. As a result, a new user is displayed on the **Users** → **Management** tab.

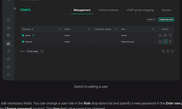


User is added

Edit a user

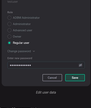
To edit user data, follow the steps:

1. Click the icon in the **Actions** column on the **Users** → **Management** tab.



Switch to editing a user

2. In the window that opens, edit necessary fields. You can change a user role in the **Role** drop-down list and specify a new password in the **Enter new password** field (which is displayed after you open the **Change password** section). The **User** field value cannot be changed.



Edit user data

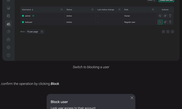
3. Click **Save**. As a result, the user data is updated on the **Users** → **Management** tab.

User data is updated

Block a user

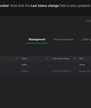
To block a user, follow the steps:

1. Click the icon in the **Actions** column on the **Users** → **Management** tab.



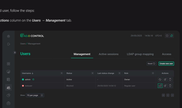
Switch to blocking a user

2. In the window that opens, confirm the operation by clicking **Block**.



Confirm the operation

As a result, the user status is changed from **Active** to **Blocked**. Note that the **Last status change** field is also updated on the **Users** → **Management** tab.

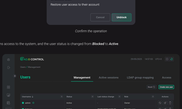


User is blocked

Unblock a user

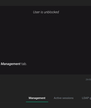
To activate a previously blocked user, follow the steps:

1. Click the icon in the **Actions** column on the **Users** → **Management** tab.



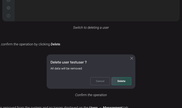
Switch to unblocking a user

2. In the window that opens, confirm the operation by clicking **Unblock**.



Confirm the operation

As a result, the user regains access to the system, and the user status is changed from **Blocked** to **Active**.

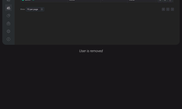


User is unblocked

Delete a user

To delete an existing user, follow the steps:

1. Click the icon in the **Actions** column on the **Users** → **Management** tab.



Switch to deleting a user

2. In the window that opens, confirm the operation by clicking **Delete**.

Confirm the operation

As a result, the user data is removed from the system and no longer displayed on the **Users** → **Management** tab.

User is removed

LDAP authentication

Daria Barysheva

AD.B CONTROL

To Table of Contents

ADB Control supports Lightweight Directory Access Protocol (LDAP) user authentication. Unlike basic authentication, you do not need to add users manually via ADB Control when using LDAP. User accounts and passwords are checked on the selected LDAP server.

To configure LDAP authentication, follow the steps:

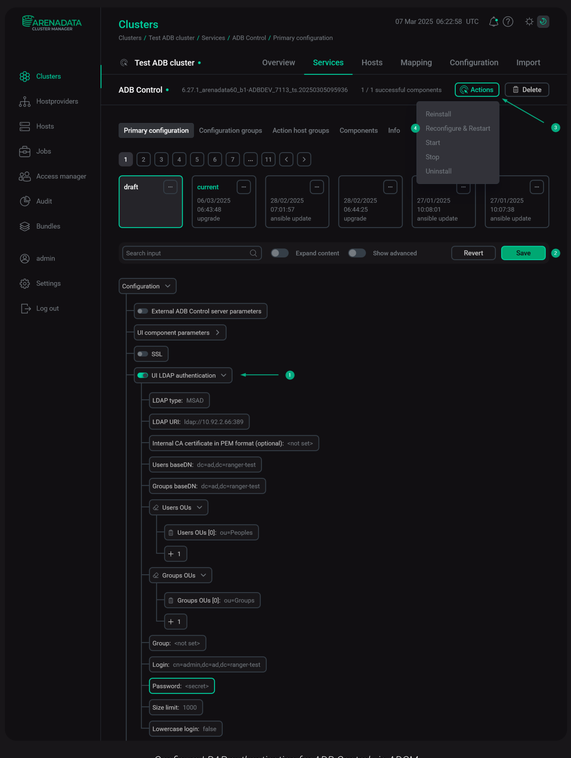
1. Ensure the target LDAP server is configured and available. ADB Control supports two LDAP implementations: Microsoft Active Directory (MS AD) and 389 Directory server as a part of FreeIPA.
2. Open the ADB Control service configuration page in ADCM.
3. Activate the ***UI LDAP authentication*** switcher.
4. Fill in the following fields.

Field	Description	Example in MS AD
LDAP type	A type of the LDAP server. Possible values: ▪ `MSAD` — Microsoft Active Directory; ▪ `FreeIPA` — 389 Directory server as a part of FreeIPA.	MSAD
LDAP URI	A URI for connecting to the LDAP server. Requires the following format: `<schema>://<host>:<port>`. For example, `ldap://example.com:389`, `ldaps://example.com:636`. If a port number is not specified, the standard ports are used: `389` for LDAP and `636` for LDAPS	ldap://10.92.2.66:389
Internal CA certificate in PEM format (optional)	The internal CA certificate or certificate chain in PEM format that signed the LDAP server certificate	—
Users baseDN	A limitation of the search scope of objects in the LDAP directory that is used in users search requests	dc=ad,dc=ranger-test
Groups baseDN	A limitation of the search scope of objects in the LDAP directory that is used in groups search requests	dc=ad,dc=ranger-test
Users OUs	A list of `OU` for user search. If the option is set, users will be searched only in the specified OUs, otherwise — within full ***Users baseDN***. Enter each `OU` value on a separate line using the `ou=<name>` format (e.g. `ou=users1`)	ou=Peoples
Groups OUs	A list of `OU` for group search. If the option is set, groups will be searched only in the specified OUs, otherwise — within full ***Groups baseDN***. Enter each `OU` value on a separate line using the `ou=<name>` format (e.g. `ou=groups1`)	ou=Groups
Group	A group name that is used for service requests to the LDAP server	—
Login	A user name that is used for service requests to the LDAP server	cn=admin,dc=ad,dc=ranger-test
Password	A user password that is used for service requests to the LDAP server	A password of the `admin` user
Size limit	A maximum number of records that can be returned by the LDAP server	1000
Lowercase login	Defines whether to convert user names to lowercase	false

IMPORTANT

- Different LDAP implementations use different names for object types and identifiers. It is recommended to refine the settings format for a specific LDAP implementation from the LDAP server administrator.
- To use LDAP over SSL (LDAPS) starting with ADB Control 4.10.3, do the following:
  - Use the `ldaps` protocol in the ***LDAP URI*** field.
  - Fill in the ***HTTPS parameters enable*** section.
  - Fill in the ***Internal CA certificate in PEM format (optional)*** field. The certificate should be replicated to all hosts used by ADB Control (imported to *truststore.jks*).

5. Click ***Save***. Then apply the ***Reconfigure & Restart*** action to the ADB Control service.



Configure LDAP authentication for ADB Control via ADCM

6. In the ADB Control web interface, map LDAP user groups to ADB Control roles. This is necessary for LDAP users to get the appropriate permissions to work in ADB Control. For more information, see Authorization.

If all steps are completed successfully, users can connect to ADB Control using the accounts registered for them on the LDAP server.

Roles and access permissions

Each user is assigned a role that determines their access level in AccessControl. The Administrator allows you to control access to the various functions of the system depending on the assigned role and level.

Currently, AC PRO comes supports the following roles:

- **Owner**: Owner
- **Administrator**: Administrator
- **Operator**: Operator
- **LDAP Administrator**: LDAP administrator
- **Advanced User**: User with Advanced permissions
- **Regular User**: Regular user

NOTE

To log in with the **Read Only** role, must be associated with the same name. **READ** is a LDAP or Network of a Domain, which grants users the minimum level of permissions necessary to view the system configuration.

You will be shown only the destination of access rights between the advanced-level roles.

IMPORTANT

The Advanced group management Roles and capabilities in AD is similar to AC's system of the Advanced LDAP Control centers. AC Support for the functionality Advanced Advanced management Roles and capabilities.

View sessions	Ability to view the Sessions > Sessions page. Click Sessions > Sessions to view the Sessions > Sessions page.	No	No	No	Yes	Yes	Yes
Change user sessions	Ability to change user sessions. Click Sessions > Active sessions to change user sessions.	No	No	No	No	Yes	Yes

Configure role mappings with LDAP groups

Role mappings are used to map LDAP groups to AccessControl roles. Click Access > LDAP role mapping to configure any specific role mappings with LDAP groups. You will be able to select a LDAP domain, and you can then map LDAP groups to the ADM Control roles listed above.

You can manage user mappings in the Users > LDAP role mapping tab.

The Users > LDAP group mapping tab

Add a mapping

To add a new mapping, follow the steps:

1. Click Create new mapping in the Users > LDAP group mapping tab.

Button for adding a mapping

2. In the domain field, specify FQ the following fields:
   - **Group**: Enter the name of the LDAP group. It will be shown in the LDAP group field once the application finds the LDAP group.
   - **Role**: Select a LDAP Control.

NOTE

Each LDAP group can be mapped only to one role in ADM Control.

New LDAP group mapping

3. Click **Save**. By default, a new mapping is displayed in the Users > LDAP group mapping tab.

Mapping is added

Edit a mapping

To edit an existing mapping, follow the steps:

1. Hover over the mapping in the Users > LDAP group mapping tab.

Button for editing a mapping

2. Edit or delete the name with necessary fields. All fields will be given a new domain field. The **Group** field cannot be changed.

LDAP mapping

3. Click **Save**. As a result, the mapping data is updated in the Users > LDAP group mapping tab.

Mapping is updated

Delete a mapping

To delete an existing mapping, follow the steps:

1. Hover over the mapping in the Users > LDAP group mapping tab.

Button for deleting a mapping

2. In the window that opens, confirm the operation by clicking **Delete**.

Confirm the operation

As a result, the mapping is removed from the Users > LDAP group mapping tab.

Mapping is removed

Activation LDAP group names

NOTE

Activation LDAP group names will get automated password audit and real-time notification of missing mapping. The Windows account is changed. You can demand updates of LDAP group names.

Mapping of the LDAP name in your account will be activated in the Activation. Click Mapping for entering automatic name and LDAP name in the Users > LDAP group mapping tab. Click **Activate** to activate the LDAP group name.

Mapping of the LDAP name in your account will be activated in the Activation. Click **Activate** to activate the **LDAP name activation** or **RECV name activation** in the Users > LDAP group mapping tab.

1. Click **Activate**.

Confirm the action

Go to automation of LDAP group names

2. Read the information in the window that opens and confirm the action by clicking **Activate**.

Confirm the action

The name — receive LDAP

Set advanced permissions

Users with the **Advanced User** can set the access permissions for specific users to specific objects. Click Access > Advanced permissions to set the advanced permissions. You can manage user advanced permissions in the Users > Access tab in the ADM Control web interface.

The Users — Access tab

Add a permission

To add a new permission, follow the steps:

1. Click Permissions in the Users > Access tab.

Button to create a permission

2. In the window that opens, fill in the following information:
   - **Domain**: Select the domain to which the user belongs.
   - **Name**: Enter the user's name and then click it in the search results. The **Type** field will be filled in automatically.
   - **Permissions**: Select the permissions to be granted to the user.

Enter user's name

3. In the **Domain** menu, select ADM Control and database to be accessed by the user added in the previous step. To select all Control with full database, click the **Select all** flag in the top right corner.

Select all Control with full database

4. Click **Save**. By default, a new permission is displayed in the Users > Access tab.

Permission is added

Edit a permission

To edit an existing permission, follow the steps:

1. Hover over the permission in the Users > Access tab.

Button to edit a permission

2. In the window that opens, edit necessary fields. All fields will be the same as described in the **Domain** field when you entered the domain.

Edit permission

3. Click **Save**. By default, the permission data is updated in the Users > Access tab.

Permission is updated

Delete a permission

To delete an existing permission, follow the steps:

1. Hover over the permission in the Users > Access tab.

Button to delete a permission

2. In the window that opens, confirm the operation by clicking **Delete**.

Confirm the operation

As a result, permission is removed from the Users > Access tab.

Permission is removed

User sessions

Daria Barysheva

Contents

To Table of Contents

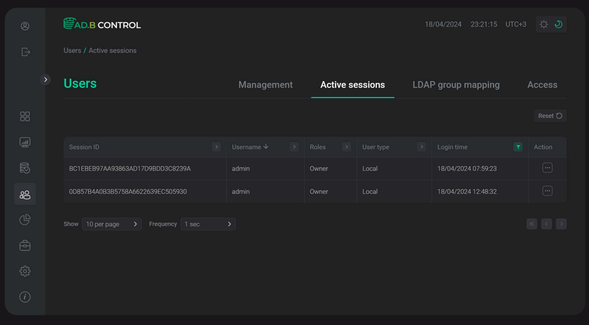
View a list of sessions

Terminate sessions

The ***Users → Active sessions*** tab is designed to monitor active sessions of ADB Control users. This page also allows you to terminate selected sessions.

View a list of sessions

On the ***Users → Active sessions*** tab, there is a table with the following information on sessions.



List of sessions

The "Users → Active sessions" tab fields

Field	Description
Session ID	A session identifier
Username	A name of the user who connected to ADB Control
Roles	A role of the user who connected to ADB Control
User type	A type of the user who connected to ADB Control. Possible values: ▪ `AD` — an LDAP user; ▪ `Local` — an ADB Control user who uses basic authentication; ▪ `System` — a system user.
Login time	A session start timestamp

In the column headers of the table with a list of sessions, there are filters that you can use to select specific data. To open a filter, click the › icon. For those columns where the set of possible values is limited (e.g. ***Roles***), you can select a value from the drop-down list. For some columns (e.g. ***Session ID***), the search value should be entered. For columns that show date and time (e.g. ***Login time***), the time range can be selected from the calendar.

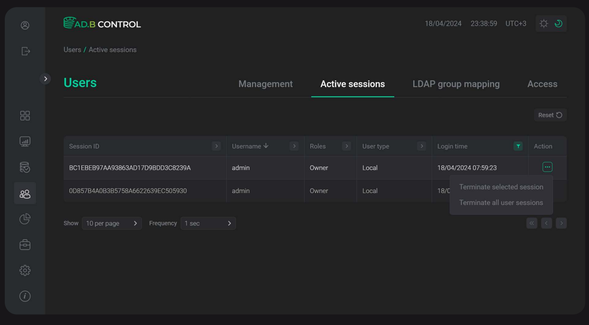
The ▼ icon means that a filter is defined for the column. To reset all filters, click ***Reset***.

Terminate sessions

NOTE

Termination of user sessions is available for ADB Control users with appropriate permissions (see `Manage user sessions` in the Authorization article).

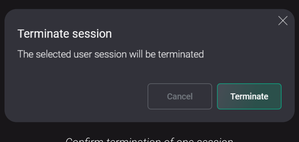
To terminate a session, click ••• in the ***Actions*** column on the ***Users → Active sessions*** tab.



Go to terminating a session

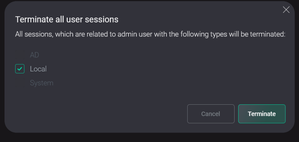
Select one of the options:

- ***Terminate selected session*** — terminates only one selected session. To confirm the action, click ***Terminate*** in the window that opens.



Confirm termination of one session

- ***Terminate all user sessions*** — terminates all sessions of the user who started the selected session. In the window that opens, you can set the user type (see ***User type*** above). To confirm the action, click ***Terminate***.



Confirm termination of several sessions

SSL encryption

AD.B CONTROL

Contents

To Table of Contents

ADB Control
External databases
- PostgreSQL
- ClickHouse

ADB Control

You can secure communication between ADB Control web server and clients using the HTTPS protocol, which is based on SSL encryption. To configure access to ADB Control via HTTPS, follow the steps:

1. Open the ADB Control service configuration page in ADCM.
2. Set the ***Show advanced*** flag.
3. Activate the ***SSL*** switcher.
4. Fill in the following fields if you need to use your own certificates.

IMPORTANT

If no settings are filled in, ADB Control will create certificates by itself.

Parameter	Description	Default value
CA certificate	Server certificate authority (CA) file contents in the CRT format (*.crt file)	—
Server certificate	Server certificate contents in the CRT format (*.crt file)	—
Server private key	Server private key contents (*.key file)	—
Verify system endpoints' certificates	A flag that indicates whether to verify certificates of system endpoints. When using the ***Verify system endpoints' certificates*** option in the ADB Control configuration with self-signed certificates, ensure that you added the root and intermediate CA certificates to the OS trusted root certificate stores. In order to use the ***Verify system endpoints' certificates*** option with your own certificates, for proper verification, add the ADB Control IP address to the `CN` field of the *san.cnf* file (`SAN`) and exclude DNS from the `alt_names` section (leave only IP)	false
Server JKS keystore path	A path to the keystore file in the JKS format for the ADB Control server part. For example, */opt/adcc/ssl/keystore.jks*	—
Server JKS keystore password	A password that is used for connecting to ***Server JKS keystore path***	—
Server JKS truststore path	A path to the truststore file in the JKS format for the ADB Control server part. For example, */opt/adcc/ssl/truststore.jks*	—
Server JKS truststore password	A password that is used for connecting to ***Server JKS truststore path***	—
Client JKS keystore path	A path to the keystore file in the JKS format for the ADB Control client part (ADB Control/ADBM agents). For example, */opt/ssl/keystore.jks*	—
Client JKS keystore password	A password that is used for connecting to ***Client JKS keystore path***	—
Client JKS truststore path	A path to the truststore file in the JKS format for the ADB Control client part (ADB Control/ADBM agents). For example, */opt/ssl/truststore.jks*	—
Client JKS truststore password	A password that is used for connecting to ***Client JKS truststore path***	—

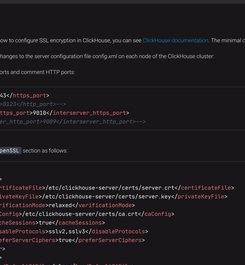
Fill in the SSL parameters

Recommendations

- The *adcc_ca.crt*, *adcc.crt*, and *adcc.key* files are created by default on the host where ADB Control is deployed. They are located in the */opt/adcc/ssl* folder. You can specify these files for testing purposes.
- For production systems, you should use a trusted certificate authority (CA) to sign certificates. To create a real SSL certificate and register it with the CA, use the `openssl` utility.
- In case of expanding ADB, SSL certificates should be re-generated to add the corresponding `ServerAltNames` for new ADB hosts.
- To connect an external ADB cluster to existing ADB Control with SSL enabled, certificates with `ServerAltNames` for hosts of both ADB clusters should be specified in the settings of a main and an external ADB cluster.
- To hide the truststore password in Vault, set the ***Use PEM CA for vault*** parameter in the ***Vault integration*** section of the ADB cluster configuration to `true`.
- In the ***CA certificate*** field, it is necessary to enter certificate chains from the root and intermediate CA for the correct cluster operation.
  The order of PEM CA certificates in the chain should be as follows:
  - Sub-CA Certificate — start.
  - Root CA Certificate — end.

  This also applies to the custom JKS created with `keytool`.
  When using ADB Control as an external system, ensure that the client truststore contains CA from the server.

5. Click **Save**.
6. Apply the ***Reconfigure & Restart*** action to the ADB Control service.



Apply changes

After all steps are completed successfully, the ADB Control server port (by default, `81`) will be used for SSL. The ADB Control address will look as follows: *https://<ADB Control IP address>:81*.

External databases

Starting with ADB Control 4.11.0, after you enable SSL as described above, SSL encryption is automatically used for connections to internal databases of ADB Control and ADBM. If external databases are used in ADB Control (Metrics DB (ClickHouse), Query DB (PostgreSQL), or Offload DB (PostgreSQL)) and/or external PostgreSQL is used in ADBM, you should manually enable SSL encryption in these databases.

PostgreSQL

1. Add the following options to the *postgresql.conf* file:

```
ssl = on
ssl_cert_file = '<server_crt_path>'
ssl_key_file = '<server_key_path>'
```

where:

- `<server_crt_path>` – a path to the server certificate on the PostgreSQL server. For example, */pg_data1/adpg14/server.crt*.
- `<server_key_path>` – a path to the server private key on the PostgreSQL server. For example, */pg_data1/adpg14/server.key*.

2. Add the following entry to the *pg_hba.conf* file:

```
hostssl    all  all       0.0.0.0/0      md5
```

3. Restart PostgreSQL to apply changes.
4. To ensure that SSL is successfully configured, you can connect to PostgreSQL via `psql`. When connecting, define the following options: `-U` – user name, `-d` – database, `-h` – host IP.

```
$ psql -U adcc -d metrics -h 10.92.41.125
```

After you enter the user password, the following information should be displayed:

```
SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256, compression: off)
```

5. Perform standard actions to configure external PostgreSQL for ADB Control or ADBM. If you configure Offload DB, refer to Configure job policies → Metrics offload.

IMPORTANT

- To fill in the `<server_crt_path>` and `<server_key_path>` fields, you should first generate your own certificate and key accordingly. You can also reuse the certificate and key generated by ADB Control (see *adcc.crt* and *adcc.key* in ADB Control). But it is important that the ***SSL*** section in the ADB Control configuration contains the same certificates that are specified in the PostgreSQL file *postgresql.conf*.
- The current implementation does not provide authentication based on client certificates, only SSL encryption of traffic is provided. For this reason, the `md5` authentication type is used in *pg_hba.conf*, not `cert`. Also, it is not required to enter a CA certificate in the `ssl_ca_file` field of the *postgresql.conf* file.
- If ADPG is used as external PostgreSQL, you can configure SSL (including certificates generation) according to the Enable SSL encryption article.

ClickHouse

For more information on how to configure SSL encryption in ClickHouse, you can see ClickHouse documentation. The minimal configuration steps are listed below:

1. Apply the following changes to the server configuration file *config.xml* on each node of the ClickHouse cluster:
   - Enable HTTPS ports and comment HTTP ports:

```
<https_port>8443</https_port>
<!--<http_port>8123</http_port>-->
<interserver_https_port>9010</interserver_https_port>
<!--<interserver_http_port>9009</interserver_http_port>-->
```

   - Configure the `OpenSSL` section as follows:

```
<openSSL>
    <server>
        <certificateFile>/etc/clickhouse-server/certs/server.crt</certificateFile>
        <privateKeyFile>/etc/clickhouse-server/certs/server.key</privateKeyFile>
        <verificationMode>relaxed</verificationMode>
        <caConfig>/etc/clickhouse-server/certs/ca.crt</caConfig>
        <cacheSessions>true</cacheSessions>
        <disableProtocols>sslv2,sslv3</disableProtocols>
        <preferServerCiphers>true</preferServerCiphers>
    </server>
    <client>
        <loadDefaultCAFile>false</loadDefaultCAFile>
        <caConfig>/etc/clickhouse-server/certs/ca.crt</caConfig>
        <cacheSessions>true</cacheSessions>
        <disableProtocols>sslv2,sslv3</disableProtocols>
        <preferServerCiphers>true</preferServerCiphers>
        <verificationMode>relaxed</verificationMode>
        <invalidCertificateHandler>
            <name>RejectCertificateHandler</name>
        </invalidCertificateHandler>
    </client>
</openSSL>
```

     where the following paths are used (can be different in your environment):
     - */etc/clickhouse-server/certs/server.crt* – a path to the server certificate on the ClickHouse node.
     - */etc/clickhouse-server/certs/server.key* – a path to the server private key on the ClickHouse node.
     - */etc/clickhouse-server/certs/ca.crt* – a path to the CA certificate on the ClickHouse node.

2. Restart ClickHouse to apply changes.
3. Perform standard actions to configure external ClickHouse for ADB Control.

IMPORTANT

To fill in the `<certificateFile>` and `<privateKeyFile>` fields, you should first generate your own certificate and key accordingly. You can also reuse the certificate and key generated by ADB Control (see *adcc.crt* and *adcc.key* in ADB Control). But it is important that the ***SSL*** section in the ADB Control configuration contains the same certificates that are specified in the ClickHouse file *config.xml*.

Configure job policies for the [DPS server](#) and [Hub](#) and define what you want to get forwarded to different appenders. The page includes two types of policies:

- [Data cleanup](#)
- [Metrics offload](#)

Data cleanup

On the **Configuration** > **Job policies** > **Data cleanup** tab, you can define a schedule for cleaning data from [H2DB](#) (Hub):

To configure Data cleanup:

1. Enable the **Schedule** switch.
2. Enter a **Cron expression**.
3. Enter a **Retention** period for each data type.

Field	Description	Default value
Next run	A read-only field that shows the next execution time.	
Cron expression	Specifies when and how often to perform data cleanup. Use a [Quartz cron expression](#) in the following format: `seconds minutes hours day-of-month month day-of-week [year]` Examples: `0 0 0 * * ?` – Every day at midnight `0 0 */6 * * ?` – Every 6 hours `0 30 2 * * ?` – Every day at 2:30 AM `0 0 0 1 * ?` – First day of every month `0 0 0 * * MON` – Every Monday Examples: `0/30 - 59 - 14` – Every minute starting at 14, every 30 minutes until the end of the hour	`0 0 0 * * ?`
Data cleanup retention	Specify how long to keep data for each type. Enter a number and select a unit: `Days`, `Hours`, `Minutes`, or `Seconds`.	`Metrics`: 7 days `Logs`: 7 days `Events`: 7 days `Traces`: 7 days `Inserts`: 7 days

Click **Save**. The **Next run** field updates to show the next scheduled execution.

Cron help

- Click the **Cron expression** field to open a cron helper dialog.
- Use the dialog to build a valid Quartz cron expression without memorizing the syntax.
- Click **Apply** to insert the generated expression into the field.

Metrics offload

Configuration

On the **Configuration** > **Job policies** > **Metrics offload** tab, you can configure offloading of metrics from [H2DB](#) (Hub) to [VictoriaMetrics](#).

To configure Metrics offload:

1. Enable the **Schedule** switch.
2. Enter a **Cron expression** to define when offloading runs.
3. Enter a **Retention** period for metrics to keep in H2DB. Use a number and select `Days`, `Hours`, `Minutes`, or `Seconds`.

Field	Description	Default value
Next run	A read-only field that shows the next execution time.	
Cron expression	Specifies when and how often to perform offloading. Use a [Quartz cron expression](#) in the following format: `seconds minutes hours day-of-month month day-of-week [year]` Examples: `0 0 0 * * ?` – Every day at midnight `0 0 */6 * * ?` – Every 6 hours `0 30 2 * * ?` – Every day at 2:30 AM `0 0 0 1 * ?` – First day of every month `0 0 0 * * MON` – Every Monday Examples: `0/30 - 59 - 14` – Every minute starting at 14, every 30 minutes until the end of the hour	`0 0 0 * * ?`
Retention	Specify how long to keep metrics in H2DB before offloading. Enter a number and select `Days`, `Hours`, `Minutes`, or `Seconds`.	`Metrics`: 7 days

Click **Save**. The **Next run** field updates to show the next scheduled execution.

Cron help

- Click the **Cron expression** field to open the cron helper dialog.
- Use the dialog to build a valid Quartz cron expression without memorizing the syntax.
- Click **Apply** to insert the generated expression into the field.

Structure of offloaded data

Offloaded metrics are stored in [VictoriaMetrics](#) and can be queried using [MetricsQL](#). For example, to retrieve [JVM](#) metrics for a specific [Runtime](#), use:

```
{__name__=~"jvm_.*", runtime="<runtime_name>"}
```

Where `<runtime_name>` is the name of the runtime as shown in the **Runtimes** list.

Logs

The table below lists logs configured in [H2DB](#) (Hub) to be sent to [VictoriaLogs](#). For more information on the data stored and how to query it, see the [Explore logs](#) page.

Column	Description
id	A unique identifier of the configuration record.
name	An event timestamp.
enabled	Indicates whether the configuration is active.
version	A read-only timestamp of the version when the record was last saved.
description	An optional description of the configuration's purpose.
level	The minimum log level to capture. Options: `TRACE`, `DEBUG`, `INFO`, `WARN`, `ERROR`.
logger	The name of the logger to capture. Leave empty to capture logs from all loggers.
thread	The name of the thread to capture logs from. Leave empty to capture logs from all threads.
message	A regular expression pattern to match against log messages. Leave empty to capture all messages.

Logs with JSR

The table below lists logs configured in [H2DB](#) (Hub) to be sent to [VictoriaLogs](#). For more information on the data stored and how to query it, see the [Explore logs](#) page.

Column	Description
id	An identifier of the configuration record. Click [Add](#) or [Edit](#).
name	An event timestamp.
enabled	Indicates whether the configuration is active.
version	A read-only timestamp of the version when the record was last saved.
description	An optional description of the configuration's purpose.
level	The minimum log level to capture. Options: `TRACE`, `DEBUG`, `INFO`, `WARN`, `ERROR`.
logger	The name of the logger to capture. Leave empty to capture logs from all loggers.
thread	The name of the thread to capture logs from. Leave empty to capture logs from all threads.
message	A regular expression pattern to match against log messages. Leave empty to capture all messages.

Logs appenders

The table below lists logs appenders in [H2DB](#) (Hub). For more information on the data stored and how to query it, see the [Explore logs](#) page.

Column	Description
id	A unique identifier. Click [Add](#) or [Edit](#).
name	A unique name of the appender.
appender	A type of the appender. Options: `JSON` – Formats logs as JSON for structured logging. `GELF` – Graylog Extended Log Format for Graylog integration. `SYSLOG` – Sends logs to a syslog server. `CONSOLE` – Outputs logs to the console. `FILE` – Writes logs to a file. `ROLLING_FILE` – Writes logs to a file with rotation.
appender_type	A type of the appender that can be applied to. Options: `Runtime` – Applies to runtime logs. `Server` – Applies to server logs. `Hub` – Applies to hub logs. `Universal` – Applies to all log types.

appender_target	An optional target for the appender. Options:
	`Runtime`
	`Server`
	`Hub`
	`Universal`

appender_level	An optional level for the appender. Options:
	`Runtime`
	`Server`
	`Hub`
	`Universal`

appender_runtime	An optional runtime name.
pattern	A pattern for the log format.
file_path	A file path for `FILE` and `ROLLING_FILE` appenders.
max_file_size	A maximum file size for `ROLLING_FILE` appenders.
max_history	A maximum number of files to keep for `ROLLING_FILE` appenders.
syslog_host	A host for `SYSLOG` appenders.
syslog_port	A port for `SYSLOG` appenders.

syslog_facility	A facility for `SYSLOG` appenders. Options:
	`KERN`
	`USER`
	`MAIL`
	`DAEMON`
	`AUTH`
	`SYSLOG`
	`LPR`
	`NEWS`
	`UUCP`
	`CRON`
	`AUTHPRIV`
	`FTP`
	`LOCAL0`
	`LOCAL1`
	`LOCAL2`
	`LOCAL3`
	`LOCAL4`
	`LOCAL5`
	`LOCAL6`
	`LOCAL7`

syslog_app_name	An optional app name for `SYSLOG` appenders.
version	A read-only timestamp of the version when the record was last saved.
description	An optional description of the configuration's purpose.
enabled	Indicates whether the configuration is active.

Events

The table below lists events configured in [H2DB](#) (Hub) to be sent to [VictoriaLogs](#). For more information on the data stored and how to query it, see the [Explore events](#) page.

Column	Description
id	A unique identifier. Click [Add](#) or [Edit](#).
name	A unique name.
enabled	Indicates whether the configuration is active.

Events query events

The table below lists events configured in [H2DB](#) (Hub) to be sent to [VictoriaLogs](#). For more information on the data stored and how to query it, see the [Explore events](#) page.

Column	Description
id	A unique identifier. Click [Add](#) or [Edit](#).
name	A unique name.
enabled	Indicates whether the configuration is active.
description	An optional description of the configuration's purpose.
event_type	The event type to match. Leave empty to match all event types.
source	The source to match. Leave empty to match all sources.
message	A regular expression pattern to match against event messages. Leave empty to match all messages.
version	A read-only timestamp of the version when the record was last saved.

Traces

The table below lists traces configured in [H2DB](#) (Hub) to be sent to [VictoriaTraces](#). For more information on the data stored and how to query it, see the [Explore traces](#) page.

Column	Description
id	A unique identifier. Click [Add](#) or [Edit](#).
name	A unique name.
enabled	Indicates whether the configuration is active.
description	An optional description of the configuration's purpose.
span_name	The span name to match. Leave empty to match all span names.
min_duration	The minimum duration in milliseconds. Leave empty to match all durations.
max_duration	The maximum duration in milliseconds. Leave empty to match all durations.
version	A read-only timestamp of the version when the record was last saved.

Traces query traces

The table below lists traces configured in [H2DB](#) (Hub) to be sent to [VictoriaTraces](#). For more information on the data stored and how to query it, see the [Explore traces](#) page.

Column	Description
id	A unique identifier. Click [Add](#) or [Edit](#).
name	A unique name.
enabled	Indicates whether the configuration is active.
description	An optional description of the configuration's purpose.
span_name	The span name to match. Leave empty to match all span names.
min_duration	The minimum duration in milliseconds. Leave empty to match all durations.
max_duration	The maximum duration in milliseconds. Leave empty to match all durations.
version	A read-only timestamp of the version when the record was last saved.

Inserts

The table below lists inserts configured in [H2DB](#) (Hub) to be sent to [VictoriaLogs](#). For more information on the data stored and how to query it, see the [Explore inserts](#) page.

Column	Description
id	A unique identifier. Click [Add](#) or [Edit](#).
name	A unique name.
enabled	Indicates whether the configuration is active.
description	An optional description of the configuration's purpose.

operation_type	The type of operation to match. Options:
	`INSERT`
	`UPDATE`
	`DELETE`
	`SELECT`
	`DDL`
	`BATCH`
	`CALL`
	`OTHER`

table_name	The table name to match. Leave empty to match all tables.
schema_name	The schema name to match. Leave empty to match all schemas.
min_duration	The minimum duration in milliseconds. Leave empty to match all durations.
max_duration	The maximum duration in milliseconds. Leave empty to match all durations.
version	A read-only timestamp of the version when the record was last saved.

Inserts query inserts

The table below lists inserts configured in [H2DB](#) (Hub) to be sent to [VictoriaLogs](#). For more information on the data stored and how to query it, see the [Explore inserts](#) page.

Column	Description
id	A unique identifier. Click [Add](#) or [Edit](#).
name	A unique name.
enabled	Indicates whether the configuration is active.
description	An optional description of the configuration's purpose.

operation_type	The type of operation to match. Options:
	`INSERT`
	`UPDATE`
	`DELETE`
	`SELECT`
	`DDL`
	`BATCH`
	`CALL`
	`OTHER`

table_name	The table name to match. Leave empty to match all tables.
schema_name	The schema name to match. Leave empty to match all schemas.
min_duration	The minimum duration in milliseconds. Leave empty to match all durations.
max_duration	The maximum duration in milliseconds. Leave empty to match all durations.
version	A read-only timestamp of the version when the record was last saved.

Cluster management

Nick Babadzhov

ADB CONTROL

Contents

To Table of Contents

View a list of clusters
Add a cluster
Edit a cluster connection
Set a default cluster
Archive a cluster
Configure monitoring of the selected cluster
- Databases monitoring
- GUC management
- Metric offload

ADB Control allows you to monitor multiple ADB clusters simultaneously. In this case, the target cluster (within which the ADB Control web interface will be used) and other clusters (which will send metrics to the first cluster) do not have to use the same ADCM.

To manage clusters, you can use the **Clusters** tab on the **Configuration** page in the ADB Control web interface.

View a list of clusters

The **Configuration** → **Clusters** tab displays the following information on clusters.

The Configuration → Clusters tab

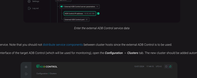
The "Configuration → Clusters" tab fields

Field	Description
Cluster name	A cluster name
Status	A cluster status • `ACTIVE` – the cluster is currently monitored. • `INTEGRATED` – the cluster monitoring is suspended.
Default cluster	For a default cluster, the `DEFAULT` label is shown. Otherwise, `No`
ADB URL	A URL of the JDBC connection
Username	A user name that is used to connect to a cluster

In the column headers of the table with a list of clusters, there are buttons that you can use to select specific data. To open a filter, click the icon. For those columns where the set of possible values is limited (e.g. **Status**), you can select a value from the drop-down list. For some columns (e.g. **Cluster name**), the search value should be entered.

The icon means that a filter is defined for the column. To reset all filters, click **Reset**.

Add a cluster

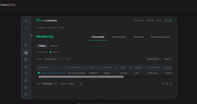


IMPORTANT

- A cluster name should be unique within ADB Control. You cannot add several clusters with the same name (for example, created via different ADCM instances).
- When upgrading clusters via ADCM, first, update the ADB cluster where the main ADB Control service is installed (not external).

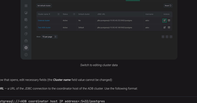
To add a new JDBC to be monitored in ADB Control, follow the steps:

1. Using ADCM, add the ADB Control service to the cluster that should be added to the existing monitoring system.
2. When configuring the service, do the following:
   - Activate the **External ADB Control service parameters** switch.
   - In the **ADB Control IP address** field, enter the IP address of the host where the target ADB Control service is deployed. As web interface is planned to be used for monitoring the main cluster, enter `0.0.0.0`.
   - In the **External ADB Control port** field, enter the port of the service the target ADB Control service is deployed. The default value is `80`.
   - Click **Save**.



Enter the external ADB Control service data

3. Install the service. Note that you should first install its service components between cluster hosts where the ADCM Control is to be used.
4. In the web interface of the main ADB Control (which will be used for monitoring), open the **Configuration** → **Clusters** tab. The new cluster should be added automatically.



Cluster is added

5. To ensure that the cluster connection is successful, you can run an SQL query in one of the cluster databases that were previously selected for monitoring, and verify that the query information appears on the **Monitoring** page. Note that the added cluster must be pre-selected in the filters on the page (if the cluster is not marked as `default`, this can use a test query, as follows:

```
SELECT pg_sleep(120);
```

Cluster is available for monitoring

Edit a cluster connection

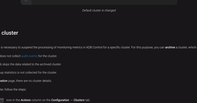
To edit cluster data, follow the steps:

1. Click the icon in the **Actions** column on the **Configuration** → **Clusters** tab.

Switch to editing cluster data

2. In the window that opens, edit necessary fields (the **Cluster name** field cannot be changed):
   - **JDBC URL** – a URL of the JDBC connection to the coordinator host of the ADB cluster. Use the following format:

     `jdbc:postgresql://<ADB coordinator host IP address>:5432/postgres`
   - **User** – a user name. Use `adcm` by default.
   - **Password** – a user password. The default user `adcm` does not require a password.



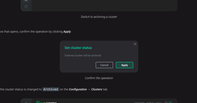
Edit cluster data

3. Click **Save** to apply changes.

Set a default cluster

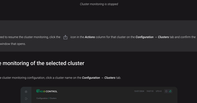
Many aspects of the ADB Control web interface have cluster-name filters. To assign the cluster to be selected in these filters by default, follow the steps:

1. Click the **Set default cluster** on the **Configuration** → **Clusters** tab.



Switch to setting a default cluster

2. In the window that opens, select a default cluster from the **Cluster name** drop-down list.



Select a default cluster

3. Click **Save**. As a result, the **Default cluster** column in the table of clusters displays `DEFAULT` for a new default cluster and `No` – for a previous default cluster.

Default cluster is changed

Archive a cluster

In some cases, it is necessary to suspend the processing of monitoring metrics in ADB Control for a specific cluster. For this purpose, you can **archive** a cluster, which means:

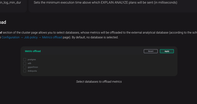
- ADB Control does not collect audit events for the cluster.
- The cluster's jar-dump files stay related to the archived cluster.
- Resource group statistics is not collected for the cluster.
- On the **Information** page, there are no cluster details.

To archive a cluster, follow the steps:

1. Click the icon in the **Actions** column on the **Configuration** → **Clusters** tab.

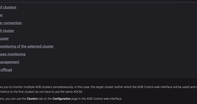
Switch to archiving a cluster

2. In the window that opens, confirm the operation by clicking **Apply**.



Confirm the operation

3. As a result, the cluster status is changed to `INTEGRATED` on the **Configuration** → **Clusters** tab.



Cluster monitoring is stopped

NOTE

If you later need to resume the cluster monitoring, click the icon in the **Actions** column for that cluster on the **Configuration** → **Clusters** tab and confirm the action in the window that opens.

Configure monitoring of the selected cluster

To navigate to the cluster monitoring configuration, click a cluster name on the **Configuration** → **Clusters** tab.

Go to the cluster configuration

The top of the opened page displays a cluster name, the `DEFAULT` label (if a cluster is selected by default), and a number of control elements for a quick transition to the actions described above:

- **Make default** – make a cluster default.
- – a cluster is default.
- – activate an archived cluster.
- – make a cluster connection.

Test ADB cluster **reset** Disabled

Available cluster actions

The main part of the opened page contains several sections that are described below. To apply any changes to the parameters in these sections, click **Apply** in the appropriate section, to undo the changes that have not been yet saved – click **Reset**.

Databases monitoring

In the **Databases monitoring** section on the cluster page, you can select databases that should be monitored in ADB Control. By default, all databases are selected.

Select databases for monitoring

GUC management

In the **GUC management** section on the cluster page, you can configure values of the GUC that control ADB Control behavior.

Configure GUC's

Available GUC's are shown in the table below:

GUCs that manage ADB Control behavior

GUC name	GUC description
adcc.monitor_timer_quiet-ness	Send timer quarrey metrics to ADCC
adcc.monitor_utility_timer-quiet-ness	Send utility timer quarrey metrics to ADCC
adcc.explain_log_buffers	Log buffers usage for EXPLAIN ANALYZE plan
adcc.explain_log_timing	Collect timing data, not just row counts for EXPLAIN ANALYZE plan
adcc.explain_log_analyze	Send EXPLAIN ANALYZE at the end of the query
adcc.explain_log_verbose	Use VERBOSE for EXPLAIN ANALYZE plan
adcc.explain_log_min_duration	Sets the minimum execution time above which EXPLAIN ANALYZE plans will be sent (in milliseconds)

Metric offload

The **Metric offload** section of the cluster page allows you to select databases, whose metrics will be offloaded to the external analytical database (according to the schedule that is configured on the `Configuration` → `ADCM` → `Metric offload` page). By default, no database is selected.

Select databases to offload metrics

Configure security policies

Daria Barysheva

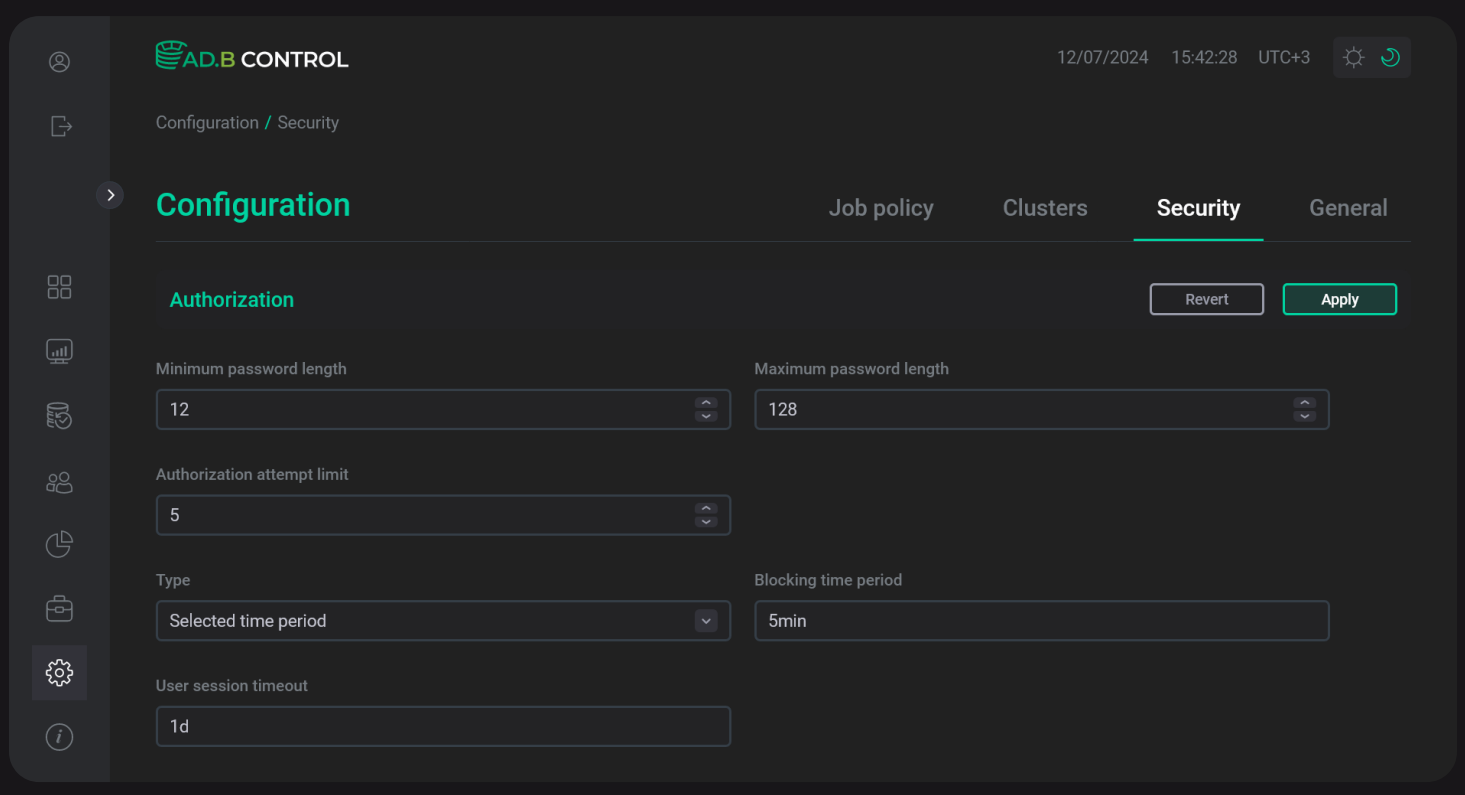
To Table of Contents

The ***Security*** tab on the ***Configuration*** page in the ADB Control web interface allows you to configure security policies. On this tab, you can define the following restrictions, which will be checked during user creation and authorization.

The "Configuration → Security" tab fields

Field	Description	Default value
Minimum password length	The minimal password length for user creation	12
Maximum password length	The maximum password length for user creation	128
Authorization attempt limit	The maximum number of failed login attempts that permanently or temporarily blocks the user (depending on the ***Type*** value)	5
Type	The blocking type that is to be used when the maximum number of failed logon attempts (***Authorization attempt limit***) is reached. Possible values: ▪ `Permanently` — block permanently until the system owner performs unblocking. ▪ `Selected time period` — block temporarily for the time specified in the ***Blocking time period*** field (or until the system owner performs unblocking).	Selected time period
Blocking time period	The temporary user blocking period in the `<value><unit>` format (without spaces), where `<unit>` has the following possible values: ▪ `min` — minutes; ▪ `hr` — hours; ▪ `d` — days. Examples: `5min`, `1hr`, `1d`	5min
User session timeout	The timeout after which ADB Control user sessions should be terminated. Requires the same format as the ***Blocking time period*** field	1d

To change the default settings, edit the fields and click ***Apply***. Click ***Revert*** if you need to undo the changes that have not been yet saved by clicking ***Apply***.



The Configuration → Security tab

General settings

Daria Barysheva

Contents

To Table of Contents

General
Sessions
Metrics

The ***General*** tab on the ***Configuration*** page in the ADB Control web interface allows you to configure general-purpose settings. This page consists of three tabs, each of which is described in detail below.

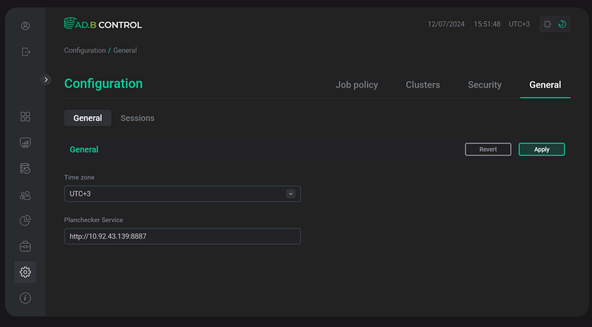
To change the default settings, edit the fields and click ***Apply***. Click ***Revert*** if you need to undo the changes that have not been yet saved by clicking ***Apply***.

General

The ***General*** tab allows you to set the general parameters.

The "Configuration → General → General" tab fields

Field	Description	Default value
Time zone	A user time zone	UTC+3
Planchecker service	Planchecker URL. This parameter is not applicable in ADB 7	—



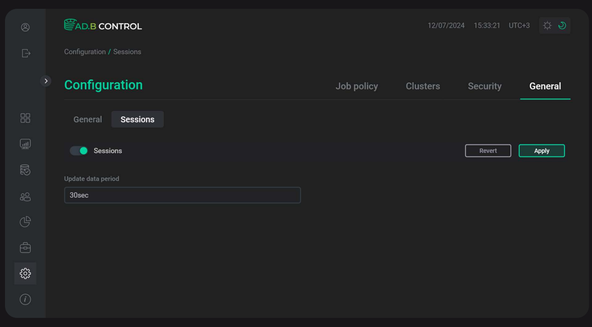
The Configuration → General → General tab

Sessions

The ***Sessions*** tab is designed to configure session monitoring.

The "Configuration → General → Sessions" tab fields

Field	Description	Default value
Sessions	A switcher that indicates whether to monitor sessions in ADB Control	True
Update data period	Indicates how often to receive information on sessions	30sec



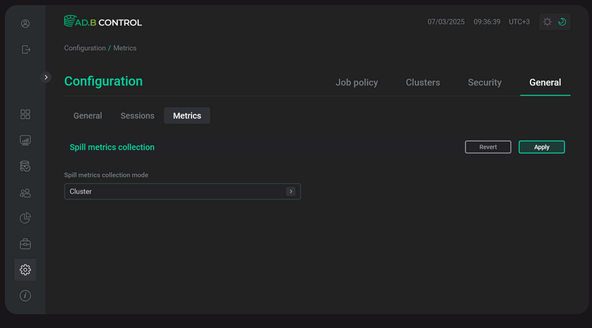
The Configuration → General → Sessions tab

Metrics

The ***Metrics*** tab allows you to configure collecting various metrics. This tab is available starting with ADB Control 4.12.0.

The "Configuration → General → Metrics" tab fields

Field	Description	Default value
Spill metrics collection mode	Mode of collecting spill file metrics: ▪ `Cluster` — only for cluster; ▪ `Cluster and segment` — for whole cluster and each segment. If the `Cluster and segment` value is selected, the ***Spill size*** and ***Spill files number*** metrics will be collected and shown for each cluster segment in the Performance section on the page with command details	Cluster



The Configuration → General → Metrics tab

Dashboard

Daria Barysheva

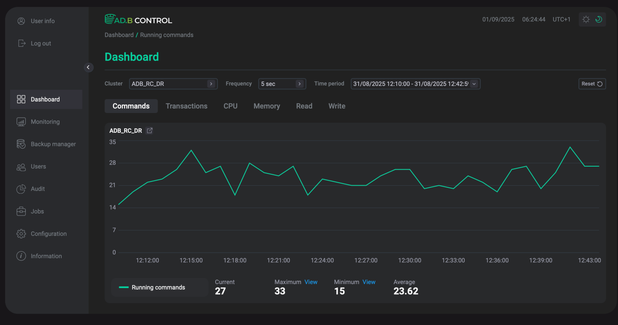
To Table of Contents

The ***Dashboard*** page in the ADB Control web interface allows you to display charts for tracking the dynamic changes of various metrics over the selected time period in the ADB clusters connected for monitoring.

Each tab on the page corresponds to a separate chart:

- ***Commands*** — a number of SQL commands in the `Running` status.
- ***Transactions*** — a number of transactions in the `Active` status.
- ***CPU*** — a total CPU consumption in the ADB cluster (percentage).
- ***Memory*** — a total virtual memory allocation in the ADB cluster (percentage).
- ***Read*** — a total data read amount in the ADB cluster (in bytes).
- ***Write*** — a total data write amount in the ADB cluster (in bytes).

To open a full screen view of any of the charts, click the icon to the right of the cluster name in the top part of the chart.

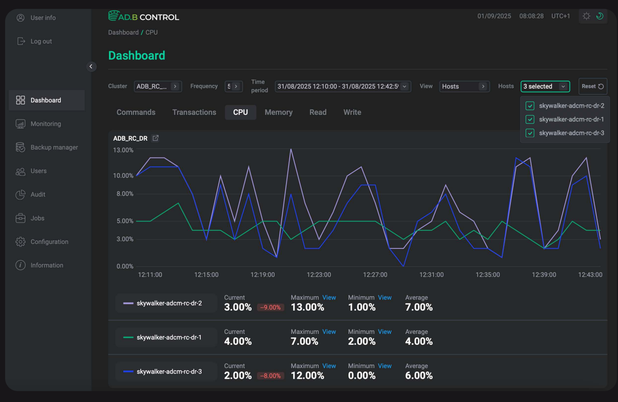


The Dashboard page

To configure charts, you can use the following fields in the top part of the page:

- ***Cluster*** — the ADB cluster for which all charts should be drawn. The default cluster can be selected in the ADB Control settings.
- ***Frequency*** — defines how often to update charts.
- ***Time period*** — the time period for which a chart is required. In the window that opens after clicking the field, you can select an interval from the offered options or set the custom time range.
- ***View*** — defines how to display charts. The field is hidden on the ***Commands*** and ***Transactions*** tabs. Possible values:
  - `Summary` — display a summary chart for the whole ADB cluster.
  - `Hosts` — display information for each cluster host in the form of separate charts.
- ***Hosts*** — the drop-down list that is used to select cluster hosts. Becomes enabled if the `Hosts` value is selected in the ***View*** field.

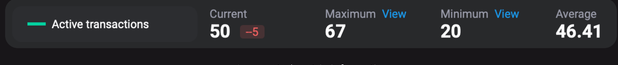
The figure below shows the option of displaying chart information in the context of cluster hosts.



Display a chart in the context of hosts

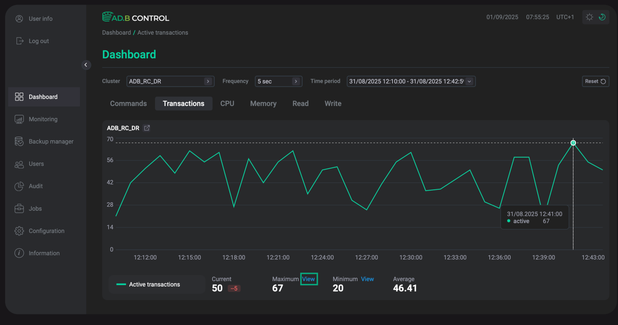
On each tab, you can see the following information under charts:

- ***Current*** — the last metric value received over the selected time period. To the right of the current value, you can see a special indicator that shows the difference between the previous and current metric values (if any).
- ***Maximum*** — the maximum metric value received over the selected time period. By clicking ***View***, you can head to the maximum value on the chart.
- ***Minimum*** — the minimum metric value received over the selected time period. By clicking ***View***, you can head to the minimum value on the chart.
- ***Average*** — the average value, which is calculated based on all metric values received over the selected time period.



Aggregated metric information

Below, you can see how to highlight the maximum or minimum metric value on the chart by clicking ***View***.



View the maximum metric value on the chart

You can also see a metric value for any other time point by hovering the mouse over the chart.

Quick

Quick overview: htop, atop, nmon, glances, dstat, vmstat, iostat, netstat, sar, mpstat, pidstat

htop - Interactive process viewer. Can be used instead of top. Allows scrolling the list vertically and horizontally to see all processes and their full command lines. Allows killing processes without typing their PIDs.

atop - Advanced system and process monitor. Has the ability to log resource consumption for later analysis. Default interval is 10 minutes but can be set to any granularity desired. Will highlight resources that are overloaded in color.

nmon - Performance monitoring tool. Allows you to toggle the display of individual resource types to make room for more detailed information. Can also record data for later analysis.

glances - Cross-platform monitoring tool written in Python. Presents a lot of information using minimal screen space. Can be run in client/server mode over a network.

dstat - Versatile replacement for vmstat, iostat and ifstat. Shows all of their information and more in addition to user and kernel statistics. Output is highly configurable through user-defined plugins for specific needs.

Uptime

uptime - Shows how long the system has been running, how many users are logged on, and system load averages for the past 1, 5, and 15 minutes.

```
$ uptime
 20:14:32 up 1 day, 23:55,  1 user,  load average: 0.00, 0.01, 0.05
```

w - Displays who is logged on and what they are doing. Header shows uptime information.

```
$ w
 20:14:37 up 1 day, 23:55,  1 user,  load average: 0.00, 0.01, 0.05
USER     TTY      FROM             LOGIN@   IDLE   JCPU   PCPU WHAT
root     pts/0    10.0.2.2         20:14    0.00s  0.03s  0.00s w
```

who - Displays who is logged on. Use who -H for column headers and who -a for extra information.

```
$ who -H
NAME     LINE         TIME             COMMENT
root     pts/0        2018-08-14 20:14 (10.0.2.2)
```

last - Displays a list of recent logins. Use last -a to have the hostname in the last column.

```
$ last -a
root     pts/0        10.0.2.2         Tue Aug 14 20:14   still logged in
reboot   system boot  4.15.0-29-generi Tue Aug 14 20:14   still running

wtmp begins Tue Aug 14 20:14:00 2018
```

lastb - Displays a list of recent failed login attempts. Use lastb -a to have the hostname in the last column. Must be run as root.

```
# lastb -a
btmp begins Tue Aug 14 20:14:37 2018
```

Memory

free - Displays total, free and used amounts of physical memory and swap space in kilobytes. Use free -m to see figures in megabytes.

```
$ free
              total        used        free      shared  buff/cache   available
Mem:        1016812       71180      660284        1004      285348      787116
Swap:       1046524           0     1046524
```

Quantity

vmstat - Displays virtual memory statistics, including processes, memory, paging, block IO, traps, disks and cpu activity. Use vmstat -s to see a table of event counters and memory statistics.

```
$ vmstat
procs -----------memory---------- ---swap-- -----io---- -system-- ------cpu-----
 r  b   swpd   free   buff  cache   si   so    bi    bo   in   cs us sy id wa st
 0  0      0 660284  72116 213232    0    0     0     0   25   19  0  0 100  0  0
```

iostat - Displays CPU and input/output statistics for devices and partitions. Use iostat -x to see extended statistics.

```
$ iostat
Linux 4.15.0-29-generic (ubuntu-bionic)  08/14/2018  _x86_64_  (1 CPU)

avg-cpu:  %user   %nice %system %iowait  %steal   %idle
           0.00    0.00    0.00    0.00    0.00  100.00

Device             tps    kB_read/s    kB_wrtn/s    kB_read    kB_wrtn
sda               0.00         0.00         0.00          0          0
```

mpstat - Displays processor statistics. Use mpstat -P ALL to see statistics for all processors.

```
$ mpstat
Linux 4.15.0-29-generic (ubuntu-bionic)  08/14/2018  _x86_64_  (1 CPU)

20:14:42     CPU    %usr   %nice    %sys %iowait    %irq   %soft  %steal  %guest  %gnice   %idle
20:14:42     all    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00  100.00
```

pidstat - Displays statistics for individual tasks. Use pidstat -d to see IO statistics.

```
$ pidstat

Cancel or terminate the transaction

System metrics collected by transactions

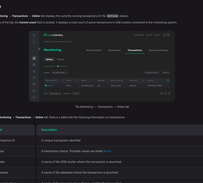
The **Table of Contents** button

The **Monitoring** → **Transactions** page in the ADB Control web interface displays the transactions that are performed in the ADB clusters connected to the monitoring system. This page includes two tabs: **Online** and **History**, each of which is described in detail below.

List of transactions

Online

On the **Monitoring** → **Transactions** → **Online** tab displays the currently running transactions (in the `ACTIVE` status). At the top of the tab, the **Current count** field is located. It displays a total count of active transactions in ADB clusters connected to the monitoring system.

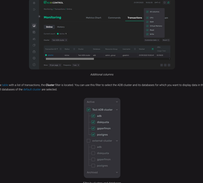


The Monitoring → Transactions → Online tab

On the **Monitoring** → **Transactions** → **Online** tab, there is a table with the following information on transactions:

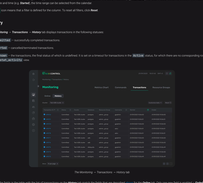
Field	Description
Transaction ID	A unique transaction identifier
Status	A transaction status. Possible values are listed above
Cluster	A name of the ADB cluster where the transaction is launched
Database	A name of the database where the transaction is launched
Resource group	A name of the resource group that is used for the transaction
Username	A name of the user who started the transaction
Started	A transaction start timestamp in the `DD/MM/YYYY HH:mm:ss` format
Type	The transaction type

If needed, you can add additional columns to the table. To do this, click **Customize table** and select a column name in the section that opens. Currently you can add system metrics that are described [below](#).



Additional columns

Above the table with a list of transactions, the **Cluster** filter is located. You can use the filter to select the ADB cluster and its databases for which you want to display data in the table. Initially, all databases of the [default cluster](#) are selected.



Filter by cluster and databases

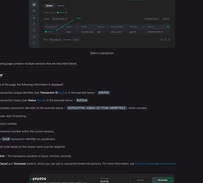
In the column headers of the table with a list of transactions, there are filters for some columns' values. To open a filter, click the [icon](#). For those columns where the set of possible values is limited (e.g. **Status**), also an option is shown that allows you to select the filter. For some columns (e.g. **Username**), the search value should be entered. For columns that show date and time (e.g. **Started**), the filter is set by a time range.

The [icon](#) means that a filter is defined for the column. To reset all filters, click **Reset**.

History

The **Monitoring** → **Transactions** → **History** tab displays transactions in the following statuses:

- `COMMITTED` — successfully completed transactions
- `ABORTED` — cancelled and failed transactions
- `UNKNOWN` — the transactions, the final status of which is undefined. It is set on a timeout for transactions in the `ACTIVE` status, for which there are no corresponding records in the `gp_distributed_xacts` table.



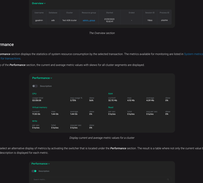
The Monitoring → Transactions → History tab

Most of the fields in the table with the list of transactions on the **History** tab match the fields that are described [above](#) for the **Online** tab. Only one new field is smallest - **Ended**, which displays a transaction completion timestamp in the `DD/MM/YYYY HH:mm:ss.msec` format. There is fixed a maximum of 10 records to be stored and to view them on all pages. Like on the **Online** tab, you have the ability to add additional columns to the table by following **customize** item.

Above the table with a list of transactions, the **Cluster** filter is located (see the description [above](#)).

Transaction details

To view the transaction details, click the transaction **Transaction ID** in the table on the **Monitoring** → **Transactions** → **Online** or **Monitoring** → **Transactions** → **History** tabs.



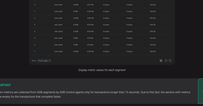
Select a transaction

The following page contains multiple sections that are described below.

Header

At the top of the page, the following information is displayed:

- The transaction unique identifier (see **Transaction ID** above), in the example below - `4764992`.
- The transaction status (see **Status** above), in the example below - `ACTIVE`.
- The complete transaction identifier on the example below - `1x4764992_0_1bdac13c-2d79-4f07-9127` - which includes:
  - cluster start timestamp;
  - session number;
  - transaction number within the current session;
  - the `0` segment identifier (identifier of coordinator);
  - hash code based on the cluster name (can be negative).
- **Run time** - the transaction execution time (see **Run time** above).
- The **Cancel** and **Terminate** buttons, which you can use to cancel/terminate transactions. For more information, see [Cancel or terminate a transaction](#).

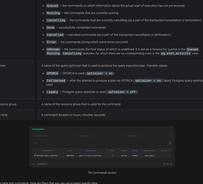


Header of the page with selected transaction

Overview

The **Overview** section displays the general transaction information. In addition to the fields mentioned [above](#), the following information is available:

- **Ended** — the transaction completion timestamp in the `DD/MM/YYYY HH:mm:ss` format. For active transactions, the field contains `-`.
- **Session ID** — an identifier of the process, within which the transaction was started.
- **Process ID** — an identifier of the process, within which the transaction was started.

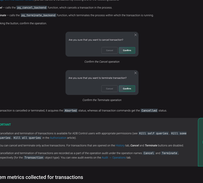


The Overview section

Performance

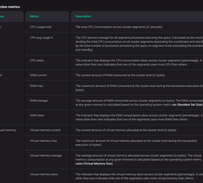
The **Performance** section displays the statistics of system resource consumption by the selected transaction. The metrics available for monitoring are listed in [System metrics collected by transactions](#).

At the top of the **Performance** section, the current and average memory values with values for all cluster segments are displayed.



Current and average values for a part of cluster segments

You can select an alternative display of metrics by activating the switcher that is located under the **Performance** section. The result is a table where not only the current value but also a detailed description is displayed for each metric.

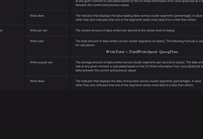


Display detailed metric descriptions

In the bottom part of the **Performance** section, the metrics values are shown separately for each cluster segment, including the coordinator segment (`Seg-1`). Letter **Segment 0** stands for the master.

Fields of the table with segment metrics

Field	Description
Segment ID	A number identifier for a segment instance. Corresponds to [`gp_segment_configuration.content`](#). For more information, see the **System catalog tables** → **gp_segment_configuration** section of the [Greenplum docs](#).
Hostname	A host name
CPU	The amount of CPU consumed by the segment (in bytes). Based on the metric values for all segments, the average value [is calculated](#).
RAM	The amount of RAM consumed by the segment (in bytes). Based on the metric values for all segments, the average value [is calculated](#).
Read (per sec)	The amount of data read per second by the segment (in bytes). Based on the metric values for all segments, the average value [is calculated](#).
Write (per sec)	The amount of data written per second by the segment (in bytes). Based on the metric values for all segments, the average value [is calculated](#).
Virtual memory	The amount of virtual memory allocated to the segment (in bytes). Based on the metric values for all segments, the average value [is calculated](#).



Display segment values for each segment

IMPORTANT

Statistics are collected from ADB segments by ADB Control agents only for transactions longer than 10 seconds. Due to this fact, the section with metrics will be empty for the transactions that complete faster.

Commands

The **Comments** section lists the commands that are performed within the current transaction.

The "Commands" tab fields

Field	Description
Command ID	A unique command identifier, which includes: • cluster start timestamp; • session number; • command number within the current session; • hash code based on the cluster name (can be negative).
SQL ID	To open the [query execution statistics](#), click the command identifier.
Command text	A command text within the current session.
Status	A command status. Possible values: • `Queued` — the command is known but information about the actual start of execution has not yet appeared; • `Running` — the command is that are currently running; • `Cancelling` — the command that are currently cancelling (as a part of the transaction cancellation or termination); • `Done` — successfully completed commands; • `Cancelled` — cancelled (as a part of the transaction cancellation or termination); • `Error` — the commands during which some errors occurred; • `Unknown` — the commands whose status is undefined. It is set on a timeout for queries in the `Queued` or `Running` status, for which there are no corresponding records in the `gp_stat_activity` table.
Plan time	A name of the query optimizer that is used to produce the query execution plan. Possible values: • `ORPHEUS` — ORCA is used (`optimizer = on`); • `POSTGRESQL` — the internal Greenplum query optimizer is used (ORCA is [disabled](#), `optimizer = off`); • `Legacy` — Postgres query optimizer is used (`optimizer = off`).
Resource group	A name of the resource group that is used for the command.
Run time	A command duration in hours, minutes, seconds.

The Commands section

Above the table with command IDs, there are filters that you can use to select specific ones:

- **Search command text** — filter by the command text (see **Command text** field). You can search by text substring of the SQL command.
- **Search CSVID** — filter by the command ID (see **Command ID** field). Enter a CSVID or its part.
- **Search SQL ID** — filter by the command ID (see **Command ID** field). Enter a SQL ID or its part.
- **Status** — filter by the command status (see **Status** above). Select a value from the drop-down list.

Cancel or terminate the transaction

On the [page with transaction details](#), you can cancel a transaction by clicking one of the following buttons:

- **Cancel** (see the [`pg_cancel_backend`](#) function) - which cancels all transactions in the session.
- **Terminate** (see the [`pg_terminate_backend`](#) function) - which terminates the process where which the transaction is running.

After clicking the button, confirm the operation.

After a transaction is cancelled or terminated, it acquires the **Aborted** status, whereas all transaction commands get the **Cancelled** status.

IMPORTANT

If the cancelled transaction of transactions is a part of the [COPY](#) operation, [`ANALYZE`](#) operation, [`VACUUM`](#) operation, [`REINDEX`](#) operation, [`CLUSTER`](#) operation, [`CREATE INDEX`](#) operation, [`ALTER TABLE`](#) operation, or [`CREATE MATERIALIZED VIEW`](#) operation, then the [Database Server Process](#) will not be killed.

You can cancel and terminate only active transactions. For transactions that are started on the [`COORDINATOR`](#) and [`SEGMENT`](#) or [`TRANSACTION`](#) levels, respectively, the [`TransactionID`](#) value is used. You can also audit events on the [`pg_stat_activity`](#) view.

System metrics collected for transactions

Both [Online](#) and [History](#) tabs allow you to view the statistics of the system resource consumption by transactions (on the [Performance](#) tab in the transaction details). The metrics available for monitoring are listed below.

NOTE

The **Online** tab displays current metric values, whereas the **History** tab shows metric values at the end of the transaction execution.

Transaction metrics

Group	Metric	Description
CPU	CPU usage total	The total CPU consumption across cluster segments (in seconds)
	CPU avg usage %	The average CPU consumption across cluster segments (in percents). Calculated as the result of dividing the total CPU consumption across cluster segments by the number of segments and by the total number of processors used by the cluster (number of processors per segment multiplied by the number of segments plus one (for coordinator)).
	CPU Skew	The indicator that displays the CPU consumption skew across cluster segments (percentage). A value other than zero indicates that one of the segments uses more CPU than others
RAM	RAM total	The total amount of RAM consumed on the cluster level (in bytes)
	RAM max	The maximum amount of RAM consumed at the cluster level during the transaction execution (in bytes)
	RAM average	The average amount of RAM consumed across cluster segments (in bytes). The calculation principle is the same as for the [**Resident set Size**] metric.
	RAM skew	The indicator that displays the RAM consumption skew across cluster segments (percentage). A value other than zero indicates that one of the segments uses more RAM than others
Virtual memory	Virtual memory current	The current amount of virtual memory allocated at the cluster level (in bytes)
	Virtual memory max	The maximum amount of virtual memory allocated at the cluster level during the transaction execution (in bytes)
	Virtual memory average	The average amount of virtual memory allocated across cluster segments (in bytes). The calculation principle is the same as for the [**Resident set Size**] metric. The [**Virtual Memory Size**] metric value (**Virtual Memory Size**)
	Virtual memory skew	The indicator that displays the virtual memory skew across cluster segments (percentage). A value other than zero indicates that one of the segments uses more virtual memory than others
Read	Read per sec	The current amount of data read per second at the cluster level (in bytes)
	Read total	The total amount of data read across cluster segments (in bytes). The following formula is used for calculation:

$$ReadTotal = TotalReadSpeed \cdot QueryTime$$

	Read avg per sec	The average amount of data read across cluster segments per second (in bytes). The data which are read from memory and not from the disk are also taken into account. For example, if the query is executed twice, then the second time it will be executed from the memory.
	Read skew	The indicator that displays the data reading skew across cluster segments (percentage). A value other than zero indicates that one of the segments reads more data from a disk than others
Write	Write per sec	The current amount of data written per second at the cluster level (in bytes)
	Write total	The total amount of data written across cluster segments (in bytes). The following formula is used for calculation:

$$WriteTotal = TotalWriteSpeed \cdot QueryTime$$

	Write avg per sec	The average amount of data written across cluster segments per second (in bytes). The data which are only present in memory and not written to disk are also taken into account. For example, if the query is executed twice, then the second time it will be executed from the memory.
	Write skew	The indicator that displays the data writing skew across cluster segments (percentage). A value other than zero indicates that one of the segments writes more data to a disk than others

Monitoring of sessions

Daria Barysheva

Contents

To Table of Contents

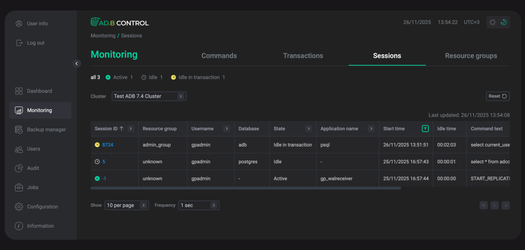
View a list of sessions

Terminate a session

The ***Monitoring*** → ***Sessions*** tab is designed to monitor current ADB sessions, both active and idle. This page also allows you to terminate specified sessions in order to release the connection pool for further connections.

View a list of sessions

On the ***Monitoring*** → ***Sessions*** tab, there is a table with the following information on sessions.



List of sessions

The "Monitoring → Sessions" tab fields

Field	Description
Session ID	A session identifier
Resource group	A resource group name
Username	A name of the user who connected to the backend
Database	A database name
State	A session state. Possible values: ■ `Active` — the backend is running a query. ■ `Idle` — the backend is waiting for a new client command. ■ `Idle in transaction` — the backend is in a transaction, but there are no currently running queries.
Application name	A name of the application that started a session
Start time	The time when the backend process was started
Idle time	An idle time (in seconds)
Command text	A text of the most recent SQL query that was run at the backend (within the current session). If `state` is `active`, the field shows the currently running query
Tags	The session tags

NOTE

To view the details of the most recent command within the current session, click the session identifier (***Session ID***). Note that you can view the command details if this command is registered in ADB Control. For more information on necessary requirements, see Monitoring of commands.

At the top of the tab, the ***Active***, ***Idle***, and ***Idle in transaction*** fields are located. They display a total count of sessions in the specified statuses.

Above the table with a list of sessions, the ***Cluster*** filter is located. You can use this filter to select the ADB cluster for which you want to display data in the table. The default cluster for all such filters is defined in the ADB Control settings.

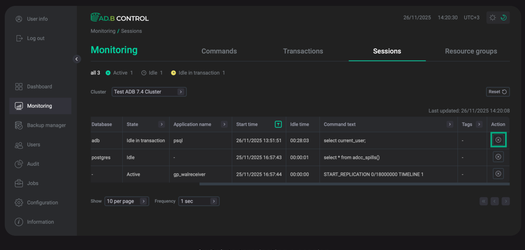
In the column headers of the table with a list of sessions, there are filters that you can use to select specific data. To open a filter, click the › icon. For those columns where the set of possible values is limited (e.g. ***State***), you can select a value from the drop-down list. For some columns (e.g. ***Session ID***), the search value should be entered. For columns that show date and time (e.g. ***Start time***), the time range can be selected from the calendar.

The ▼ icon means that a filter is defined for the column. To reset all filters, click ***Reset***.

Terminate a session

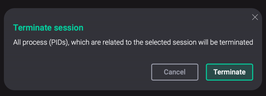
To terminate a session, follow the steps:

1. Click the ⊗ icon in the ***Actions*** column on the ***Monitoring*** → ***Sessions*** tab.



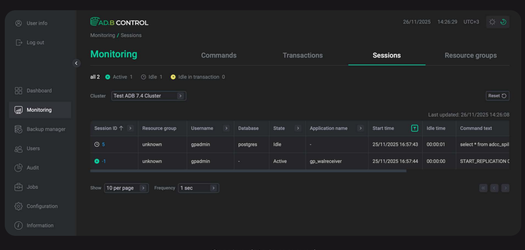
Switch to terminating a session

2. In the window that opens, confirm the operation by clicking ***Terminate***.



Confirm the operation

As a result, the session is terminated and no longer displayed on the ***Monitoring*** → ***Sessions*** tab.



Session data is removed

Work with query tags

Daria Barysheva

To Table of Contents

Starting with 4.7.5, ADB Control supports **query tagging** – assigning custom metadata to SQL queries in the form of `<key>: <values>` pairs. You can set tags for a session or transaction in ADB and then view and filter these tags on the ***Monitoring*** → ***Commands***, ***Monitoring*** → ***Transactions***, and ***Monitoring*** → ***Sessions*** pages in ADB Control. Tags are assigned to ADB queries via the `query_band` GUC. This functionality can be useful for monitoring query groups, for example, as part of the common ETL process.

Below is an example of working with query tags:

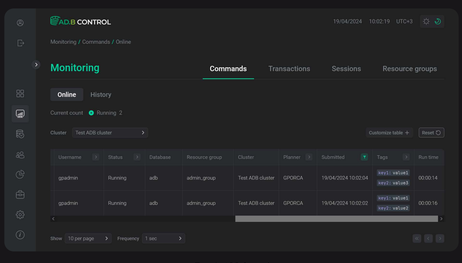
1. Open the first session in ADB (e.g. by connecting to the `adb` database on the coordinator host via `psql`).
2. Set values for two tags at the session level:

```
SET query_band = 'key1: value1,key2: value2';
```

3. Run any SQL query that lasts long enough to appear in the ADB Control web interface.
4. Within the second ADB session, set a different value for the `key2` tag:

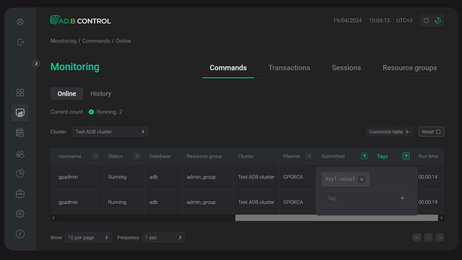
```
SET query_band = 'key1: value1,key2: value3';
```

5. Run another SQL query within the second session.
6. Go to the ***Monitoring*** → ***Commands*** → ***Queries*** → ***Online*** page in the ADB Control web UI. Tag values for both running queries are shown in the ***Tags*** column. The same column is available on the ***Monitoring*** → ***Commands*** → ***Queries*** → ***History***, ***Monitoring*** → ***Transactions*** (***Online*** and ***History***), ***Monitoring*** → ***Sessions***, and ***Monitoring*** → ***Resource groups*** → ***Statistics*** → ***<resource group>*** → ***Commands*** → ***Queueing*** pages.



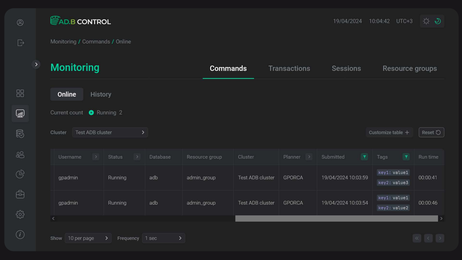
Tags in ADB Control

7. To select the queries with the specific tag value, open a drop-down list in the ***Tags*** column header, set the tag value in the ***Tag*** column as `<key>: <value>`, and click the + icon. To remove any tag from the filter, click ×.



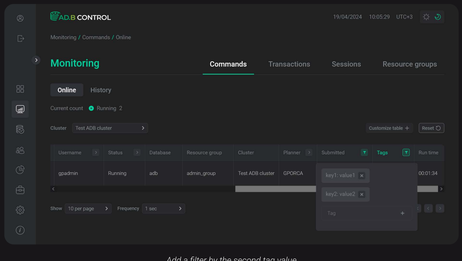
Filter by the first tag value

As a result of filtering, both queries are left on the page, because for both of them `value1` is set as the `key1` value.



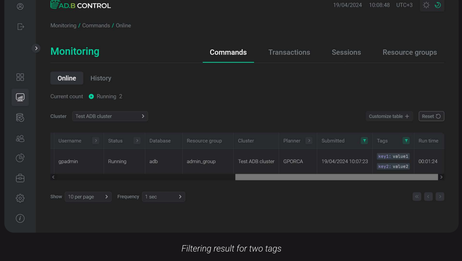
Filtering result for one tag

8. You can add a filter by the second tag value as shown below. Each tag value should be entered separately.



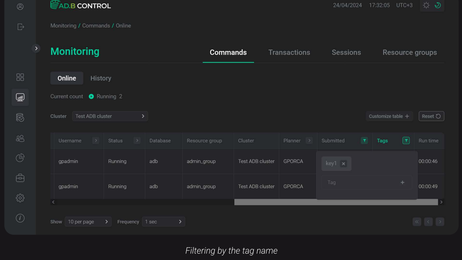
Add a filter by the second tag value

After you apply a filter, only the first session query is left on the page.



Filtering result for two tags

9. Also, you can filter data by tag names without tag values. As a result, all queries, for which the selected tag is specified, are shown, despite the tag value.



Filtering by the tag name

Audit

Audit Database Control Guide

Contents

  - [Relations](#)
  - [Operations](#)
  - [Authorizations](#)
- [ADBM](#)
  - [Clusters](#)
  - [Storages](#)
- [Table filters](#)

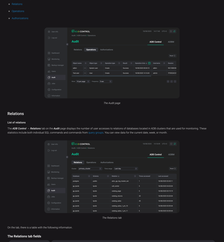
To Table of Contents

- [ADB Control](#) is available starting with [AGRAM 1.11.0].
- [ADBM](#) is available starting with [AGRAM 1.11.0].

ADB Control

The **ADB Control** page displays the following information in the form of separate [tabs]:

- [Relations](#)
- [Operations](#)
- [Authorizations](#)

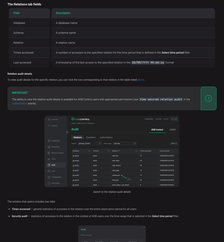


The Audit page

Relations

List of relations

Audit | Relations – **Relations** tab on the Audit page displays the number of user accesses to relations of database located in ADB clusters that are used for monitoring. These statistics include both individual SQL commands and commands from [batch jobs](#). You can also look for the current date, week, or month.



The Relations tab

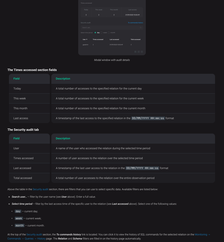
On the left, there is a table with the following information:

The Relations tab fields

Field	Description
Database	A database name
Schema	A schema name
Relation	A relation name
Times accessed	A number of user accesses to the relation since the last **Admin time period** flush
Last accessed	A timestamp of the last access to the specified relation in the `DD.MM.YYYY HH:MM:SS` format

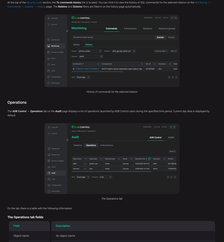
Relation audit details

To see statistics for the specific relation, you can click the icon corresponding to this relation in the table fields' [drop].



ADPortrait

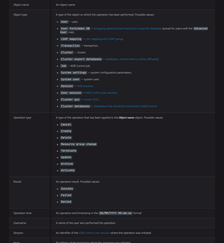
The ability to view the relation audit details in ADB Control users with appropriate permissions (see **View detailed relation audit** in the [ADPortrait] article).



Switch to the relation audit details

The window that opens shows two tabs:

- **Time accessed** – statistics of accesses to the relation over the entire period (**Admin time period**) and for the current month.
- **Access audit** – statistics of accesses to the relation for the last hour, for which users and the time range of the statistics for the **Admin time period** flush.



Initial window with audit details

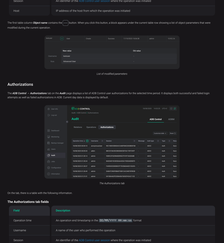
The Times accessed section fields

Field	Description
Today	A total number of accesses to the specified relation for the current day
This week	A total number of accesses to the specified relation for the current week
This month	A total number of accesses to the specified relation for the current month
Last accessed	A timestamp of the last access to the specified relation in the `DD.MM.YYYY HH:MM:SS` format
Total accessed	A total number of accesses to the relation over the entire observation period

Above the table is the [drop] of **Update**, here and there that you can use to select specific data. Available filters are listed below:

- **Audit user** – **Session** or **All** (all users) filter. Use it with care.
- **Select time period** – filter by the last access time of the specific user to the relation (**Last accessed** field). Select one of the following values:
  - **Hour** – current hour;
  - **Today** – current date;
  - **Month** – current month.

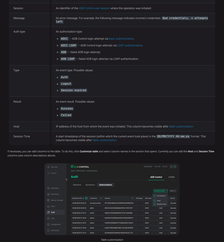
At the top of the [access audit] section, the **% commission history** link is located. You can click it to see the [% commission] for the selected relation on the **Monitoring | Commissions | Relations** tab. Otherwise, the **Relations** tab is filtered on the history page automatically.



History of commissions for the selected relation

Operations

The **ADB Control** – **Operations** tab on the **Audit** page displays a list of operations launched by ADB Control users during the specified time period. Current day data is displayed by default.



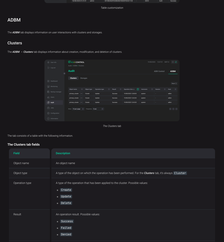
The Operations tab

On the left, there is a table with the following information:

The Operations tab fields

Field	Description
Object name	An object name
Object type	A type of the object on which the operation has been performed. Possible values: • **User** – user; • **User Permissions DB** – assigning personal permissions to a specific [attribute](#) [and for users with the **Administrator** role]; • **LDAP Selection** – [role mapping](#) with [LDAP group]; • **Transaction** – transactions; • **Cluster** – clusters; • **Cluster export information** – workspace, whose history will be affected; • **DB** – ADB control tools; • **System Settings** – system configuration parameters; • **Schedule user** – [batch user]; • **Schedule** – [batch job]; • **User session** – ADB Control user session; • **Cluster Log** – [cluster log]; • **Cluster information** – workspace that should be monitored in ADB Control.
Operation type	A type of the operation that has been applied to the **Object name** object. Possible values: • **Update**; • **Create**; • **Delete**; • **Resource group change**; • **Terminate**; • **Delete**; • **Analyze**; • **Activate**.
Result	An operation result. Possible values: • **Success**; • **Failed**; • **Denied**.
Operation time	An operation end timestamp in the `DD.MM.YYYY HH:MM:SS` format
Operation	A name of the user who performed the operation
Session	An identifier of the [ADB Control user session](#) where the operation was initiated
Host	IP address of the host from which the operation was initiated

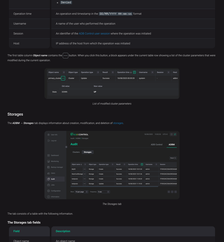
The list data sample (**Object name** column) like `Cluster: Main` you click the button, a [drop] appears under the current table row showing a list of object parameters that were modified during the current operation.



List of modified parameters

Authorizations

The **ADB Control** – **Authorizations** tab on the **Audit** page displays a list of [ADB Control user authorizations](#) for the selected time period. It always loads successful and failed login attempts, and [active sessions](#) are also displayed here if they were created in the selected period.



The Authorizations tab

On the left, there is a table with the following information:

The Authorizations tab fields

Field	Description
Operation time	An operation end timestamp in the `DD.MM.YYYY HH:MM:SS` format
Operation	A name of the user who performed the operation
Session	An identifier of the [ADB Control user session](#) where the operation was initiated
Message	Audit message. For example, the following message indicates incorrect username: **Bad credentials, 4 attempts left**.
Auth type	Authorization type. Possible values: • **ADCC** – [ADB Control login attempt](#) via [authentication]; • **ADCC LDAP** – [ADB Control login attempt](#) via [LDAP authentication]; • **ADCS** – [active ADB Control session]; • **ADB LDAP** – [login attempt](#) via LDAP authentication.
Type	An operation type. Possible values: • **Auth**; • **Logout**; • **Session expired**.
Result	An event result. Possible values: • **Success**; • **Failed**.
Session Time	IP address of the host from which the event was initiated. This column becomes visible after [drop] selection.

If necessary, you can add columns to the list. To do this, click the [drop] and select column name in the section that opens. Currently, you can add the **Host** and **Session Time** columns (see column descriptions above).

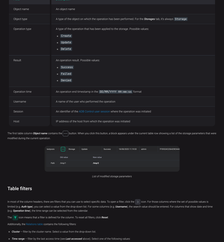


Table customization

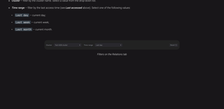
ADBM

The **ADBM** tab displays information on user interactions with clusters and storages.

Clusters

The **ADBM** – **Clusters** tab displays information about clusters, modifications, and deletion of clusters.



The Clusters tab

The tab consists of a table with the following information:

The Clusters tab fields

Field	Description
Object name	An object name
Object type	A type of the object on which the operation has been performed. For the **Clusters** tab, it's always **Cluster**.
Operation type	A type of the operation that has been applied to the cluster. Possible values: • **Create**; • **Update**; • **Delete**.
Result	An operation result. Possible values: • **Success**; • **Failed**; • **Denied**.
Operation time	An operation end timestamp in the `DD.MM.YYYY HH:MM:SS` format
Operation	A name of the user who performed the operation
Session	An identifier of the [ADB Control user session](#) where the operation was initiated
Host	IP address of the host from which the operation was initiated

The list data sample (**Object name** column) like `Cluster: Main` you click the button, a [drop] appears under the current table row showing a list of the cluster parameters that were modified during the current operation.

List of modified cluster parameters

Storages

The **ADBM** – **Storages** tab displays information about creation, modification, and deletion of [storages].

The Storages tab

The tab consists of a table with the following information:

The Storages tab fields

Field	Description
Object name	An object name
Object type	A type of the object on which the operation has been performed. For the **Storages** tab, it's always **Storage**.
Operation type	A type of the operation that has been applied to the storage. Possible values: • **Create**; • **Update**; • **Delete**.
Result	An operation result. Possible values: • **Success**; • **Failed**; • **Denied**.
Operation time	An operation end timestamp in the `DD.MM.YYYY HH:MM:SS` format
Operation	A name of the user who performed the operation
Session	An identifier of the [ADB Control user session](#) where the operation was initiated
Host	IP address of the host from which the operation was initiated

The list data sample (**Object name** column) like `Storage: Main` you click the button, a [drop] appears under the current table row showing a list of the storage parameters that were modified during the current operation.

List of modified storage parameters

Table filters

In most of the [control] tables, there are filters that you can use to select specific data. To open a filter, click the [≡] icon. For those columns where the set of available values is limited, the filter is a [drop] with a list of values. For example, in the **Operations** tab, the **Operation type** column is limited. The **Create** filter is used to display the list of operations that are of the **Create** type. For the **Operation time** column, the time range can be selected from the calendar.

The [≡] icon means that a filter is defined for the column. To reset all filters, click **Reset**.

Additionally, the [Audit] tab has the following filters:

- **Cluster** – filtering by the cluster name. Select a cluster from the drop-down list.
- **Time range** – filter by the last access time (**Last accessed** field). Select one of the following values:
  - **Current day** – current day;
  - **Current week** – current week;
  - **Current month** – current month.

Filters on the Relations tab

View jobs

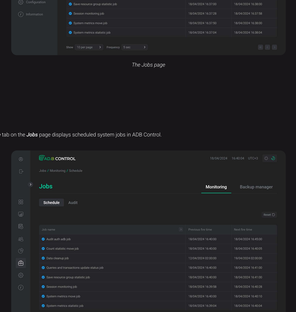
AD.B CONTROL

Contents

To Table of Contents

- Monitoring
  - Schedule
  - Audit
- Backup manager
  - Schedule
  - Audit

The **Jobs** page in the ADB Control web interface displays information on planned and completed system jobs in ADB Control/ADB Backup Manager. This page includes multiple tabs, each of which is described in detail below.

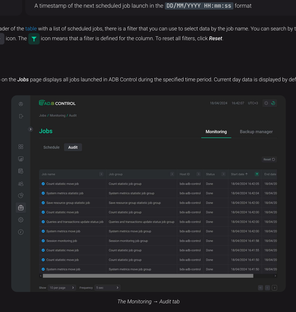


The Jobs page

Monitoring

Schedule

The ***Monitoring → Schedule*** tab on the **Jobs** page displays scheduled system jobs in ADB Control.



The Monitoring → Schedule tab

On the tab, there is a table with the following information.

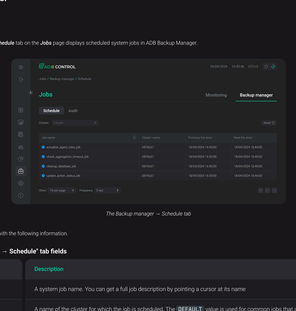
The "Monitoring → Schedule" tab fields

Field	Description
Job name	A system job name. You can get a full job description by pointing a cursor at its name
Previous fire time	A timestamp of the previous job launch in the `DD/MM/YYYY HH:mm:ss` format
Next fire time	A timestamp of the next scheduled job launch in the `DD/MM/YYYY HH:mm:ss` format

In the **Job name** column header of the table with a list of scheduled jobs, there is a filter that you can use to select data by the job name. You can search by the first characters entered. To open a filter, click the `›` icon. The `▼` icon means that a filter is defined for the column. To reset all filters, click ***Reset***.

Audit

The ***Monitoring → Audit*** tab on the **Jobs** page displays all jobs launched in ADB Control during the specified time period. Current day data is displayed by default.



The Monitoring → Audit tab

On the tab, there is a table with the following information.

The "Monitoring → Audit" tab fields

Field	Description
Job name	A job name If the job has the `Error` status, the **Job name** table column contains `...`. When you click this button, under the current table row a block appears with a message on the source error, which can be copied by clicking `Copy` in the top right corner of the block
Job group	A job group name
Host ID	An identifier of the host where the job was launched (in the `<IP address>:<port>` format)
Status	A job status. Possible values: - `Done` - `Error` - `Unknown` - `Running`
Start date	A job start timestamp in the `DD/MM/YYYY HH:mm:ss` format
End date	A job end timestamp in the `DD/MM/YYYY HH:mm:ss` format

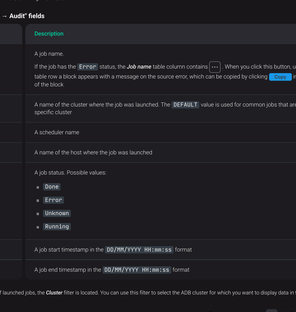
In the column headers of the table with a list of launched jobs, there are filters that you can use to select specific data. To open a filter, click the `›` icon. For those columns where the set of possible values is limited (e.g. **Job name**), you can select a value from the drop-down list. For some columns (e.g. ***Host ID***, the search value should be entered. For columns that show date and time (e.g. ***Start date***), the time range can be selected from the calendar.

The `▼` icon means that a filter is defined for the column. To reset all filters, click ***Reset***.

Backup manager

Schedule

The ***Backup manager → Schedule*** tab on the **Jobs** page displays scheduled system jobs in ADB Backup Manager.



The Backup manager → Schedule tab

On the tab, there is a table with the following information.

The "Backup manager → Schedule" tab fields

Field	Description
Job name	A system job name. You can get a full job description by pointing a cursor at its name
Cluster name	A name of the cluster for which the job is scheduled. The `DEFAULT` value is used for common jobs that are not related to any specific cluster
Previous fire time	A timestamp of the previous job launch in the `DD/MM/YYYY HH:mm:ss` format
Next fire time	A timestamp of the next scheduled job launch in the `DD/MM/YYYY HH:mm:ss` format

Above the table with a list of scheduled jobs, the ***Cluster*** filter is located. You can use this filter to select the ADB cluster for which you want to display data in the table. By default, all clusters are selected.

In the **Job name** column header of the table with a list of scheduled jobs, there is a filter that you can use to select data by the job name. You can search by the first characters entered. To open a filter, click the `›` icon. The `▼` icon means that a filter is defined for the column. To reset all filters, click ***Reset***.

Audit

The ***Backup manager → Audit*** tab on the **Jobs** page displays all jobs launched in ADB Backup Manager during the specified time period. Current day data is displayed by default.

The Backup manager → Audit tab

On the tab, there is a table with the following information.

The "Backup manager → Audit" fields

Field	Description
Job name	A job name If the job has the `Error` status, the **Job name** table column contains `...`. When you click this button, under the current table row a block appears with a message on the source error, which can be copied by clicking `Copy` in the top right corner of the block
Cluster name	A name of the cluster where the job was launched. The `DEFAULT` value is used for common jobs that are not related to any specific cluster
Scheduler name	A scheduler name
Host ID	A name of the host where the job was launched
Status	A job status. Possible values: - `Done` - `Error` - `Unknown` - `Running`
Start date	A job start timestamp in the `DD/MM/YYYY HH:mm:ss` format
End date	A job end timestamp in the `DD/MM/YYYY HH:mm:ss` format

Above the table with a list of launched jobs, the ***Cluster*** filter is located. You can use this filter to select the ADB cluster for which you want to display data in the table. By default, all clusters are selected.

In the column headers of the table with a list of launched jobs, there are filters that you can use to select specific data. To open a filter, click the `›` icon. For those columns where the set of possible values is limited (e.g. **Job name**), you can select a value from the drop-down list. For some columns (e.g. ***Host ID***, the search value should be entered. For columns that show date and time (e.g. ***Start date***), the time range can be selected from the calendar.

The `▼` icon means that a filter is defined for the column. To reset all filters, click ***Reset***.

- Agent
- Backend server
- Scheduler

Backup manager

The **Information** page in the ADB Control web interface displays the state of the ADB Control and ADMA components. This page includes multiple tabs, each of which is described in detail below.

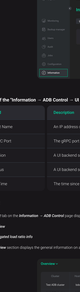
ADB Control

On the **Information** → **ADB Control** page, the status of ADB Control components is displayed.

> **NOTE**
>
> For more information on the ADB Control architecture, see Xenoquake DB Control overview.

UI backend server

The **UI backend server** tab on the **Information** → **ADB Control** page contains information on the backend server of the ADB Control web interface (UI backend server).



The Information → ADB Control → UI backend server tab

Fields of the 'Information → ADB Control → UI backend server' tab

Field	Description
Host Name	An IP address of the host where UI backend server is deployed
GRPC Port	The gRPC port that is used by UI backend server
Version	A UI backend server version
Status	A UI backend server status. The possible value is `UP`, which means that UI backend server works
Up Time	The time since the last UI backend server startup (in hours, minutes, seconds)

Agent

The **Agent** tab on the **Information** → **ADB Control** page displays information on ADB Control agents. The tab consists of the following sections:

- **Overview**
- **Aggregated load ratio info**

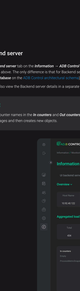
The **Overview** section displays the general information on all ADB Control agents installed on hosts of the ADB clusters that are connected to the monitoring system.

The Overview section

Fields of the Overview section

Field	Description
Cluster	A name of the ADB cluster
Host Name	A name of the host where the ADB Control agent is deployed
Version	A version of the ADB Control agent
Status	A status of the ADB Control agent. The possible value is `OK`, which means that the agent works. Stopped agents are not displayed in the table (for example, when a host is disabled)
Up Time	The time since the last agent startup in hours, minutes, seconds
Last handled message at	A timestamp of the last processed protobuf message (received from segments) in the `DD/MM/YYYY HH:mm:ss` format
Avg load rate / sec	An average number of incoming protobuf messages per second. It is calculated as a ratio of the number of messages received by the agent during the time that is defined in the `statistics` field to the value of that period

The **Aggregated load ratio info** displays the aggregated statistics on the processing of protobuf messages (received from segments) by all ADB Control agents.

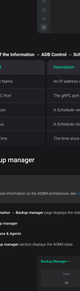


The Aggregated load ratio info section

Fields of the 'Aggregated load ratio info' section

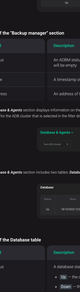
Field	Description
Total	A total number of received protobuf messages (since agent startup)
IntervalLoc	A time interval between counters sampling (in seconds). By default, `10`. You can change the limit via the `survesa.update.counter.interval` configuration parameter
Last processed messages	A number of processed messages during the last **IntervalLoc** time period
Last handled message at	A timestamp of the last processed protobuf message (in the `DD/MM/YYYY HH:mm:ss` format)
In counters	A total number of protobuf messages received from segments by ADB Control agents (since agent startup). Messages are grouped by query type (counter). The number of types for outcoming messages is displayed at the top of the list
Out counters	A total number of protobuf messages sent by ADB Control agents to Backend server (since agent startup). Messages are grouped by query type (counter). The number of types for outcoming messages is displayed at the top of the list

The information that is described above for the Overview and Aggregated load ratio info sections can be obtained for a specific ADB Control agent. To view the agent details, click the corresponding row in the **Overview** section.



Switch to the detailed agent information

All fields displayed for the selected agent are almost identical to those described above. The **Failed counters** field displays the number of out counters, which messages failed to be sent. Also note that an average load rate and all counters are calculated and displayed for the selected agent.



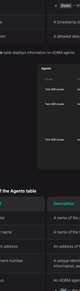
Window with agent details

Backend server

The **Backend server** tab on the **Information** → **ADB Control** page displays information on the ADB Control Backend server. The tab functionality is completely identical to the Agent tab described above. The only difference is that the Backend server ADB Control agents are the source of incoming messages, and PostgreSQL is the receiver of outcoming requests (**Query Database** in the ADB Control architecture schema).

You can also view the Backend server details in a separate window by clicking the row in the **Overview** section.

> **NOTE**
>
> The counter names in the **In counters** and **Out counters** sections may not be the same because Backend server aggregates and otherwise processes incoming messages and then creates new objects.



The Information → ADB Control → Backend server tab

Scheduler

The **Scheduler** tab on the **Information** → **ADB Control** page contains information on the ADB Control Scheduler.

The Information → ADB Control → Scheduler tab

Fields of the Information → ADB Control → Scheduler tab

Field	Description
Host Name	An IP address of the host where Scheduler is deployed
GRPC Port	The gRPC port that is used by Scheduler
Version	A Scheduler version
Status	A Scheduler status. The possible value is `UP`, which means that Scheduler works
Up Time	The time since the last Scheduler startup (in hours, minutes, seconds)

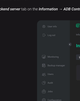
Backup manager

> **NOTE**
>
> For more information on the ADBM architecture, see Xenoquake DB Backup Manager overview.

The **Information** → **Backup manager** page displays the status of ADBM and its agents. The page consists of two sections:

- **Backup manager**
- **Database & Agents**

The **Backup manager** section displays the ADBM state.



The Backup manager section

Fields of the 'Backup manager' section

Field	Description
Status	An ADBM status. The possible value is `OK`, which means that ADBM works. If ADBM is stopped, the **Backup manager** page will be empty
Since	A timestamp of the last ADBM startup in the `DD/MM/YYYY HH:mm:ss` format
Address	An address of the host where ADBM is deployed (in the `<IP address>:<port>` format)

The **Database & Agents** section displays information on the ADB database that is connected for backing up and the ADBM agents that are installed on cluster hosts. The data is displayed for the ADB cluster that is selected in the filter directly under the section name.

Filter by clusters

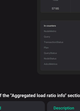
The **Database & Agents** section includes two tables: **Database** and **Agents**. The **Database** table displays information on the ADB database.

The Database table

Fields of the Database table

Field	Description
Status	A database status. Possible values: - `Up` – the database works. - `Down` – the database is stopped. In this case, the Agents table will be empty.
Since	A timestamp of the last database startup in the `DD/MM/YYYY HH:mm:ss` format
Version	A detailed description of the ADB build including PostgreSQL and Greenplum DB Database versions

The **Agents** table displays information on ADBM agents.



The Agents table

Fields of the Agents table

Field	Description
Cluster	A name of the ADB cluster
Host name	A name of the host where the ADBM agent is deployed
Agent address	An address of the host where the ADBM agent is deployed (in the `<IP address>:<port>` format)
Segment number	A unique identifier of the primary segment on the cluster. Refers to `gp_segment_configuration.content`. For more information, see Status overview
Status	An ADBM agent status. Possible values: - `Up` – the agent works. - `Down` – the agent is in the process of stopping (for example, if the host is being disconnected). The status is displayed for a short time, after which a request is sent to the Service Registry to delete the agent metadata and the agent entry is removed from the table.
Version	A version of the ADBM agent

Features

Arenadata DB Backup Manager (ADBM) is a fault-tolerant system for ADB binary backups management, which is built on the base of pgbackrest.

ADBM allows you to perform the following functions:

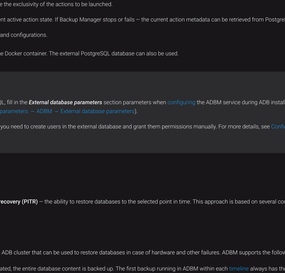
- Configure backup policies including separate schedules for different backup types.
- Create database backups according to the configured schedule and on demand.
- Maintain a list of backups with the ability to search for them and view details (including a cluster topology).
- Cleanup backups according to existing policies on a schedule and manually.
- Create restore points according to the configured schedule and manually.
- Restore databases at the moment of the selected restore point.
- Log all system actions with the ability to view details of the failed actions.
- Work with multiple ADB clusters of different types (with/without standby and mirroring).
- Use S3 and Posix compatible repositories to store backups.

NOTE

- ADBM is available in the ADB Enterprise Edition.
- Currently, ADBM can be installed only offline.

Architecture

The high-level architecture view of ADBM is shown below:



ADBM architecture

ADBM architecture is based on the following components:

- **Backup Manager**. Orchestrates cluster actions and performs background work according to the configured schedules: creates backups and recovery points, cleans up old and invalid data, etc. Backup Manager and ADB clusters interact via Backup Agents.
- **Backup Agent**. Agents are installed one per ADB cluster host. They are responsible for segment data management:
  - Run `pgbackrest` commands.
  - Manage `pgbackrest` configuration.
  - On coordinator host – manage ADB cluster operations (for example, cluster restart).
- **Service Registry**. Responsible for service discovery in ADBM. Due to Service Registry, ADBM discovers available agents (there is no pre-configured agent map in ADBM). And Backup Agents, in turn, find necessary ADBM services to send responses. Since Backup Manager can work with multiple ADB clusters at the same time — when you add a cluster, new agents are also registered via Service Registry.
- **PostgreSQL**. It is used to store the following data:
  - Cluster-wide locks to ensure the exclusivity of the actions to be launched.
  - Information about the current active action state. If Backup Manager stops or fails — the current action metadata can be retrieved from PostgreSQL.
  - Historical data on backups and configurations.

By default, it is deployed via the Docker container. The external PostgreSQL database can also be used.

NOTE

- To use external PostgreSQL, fill in the ***External database parameters*** section parameters when configuring the ADBM service during ADB installation (for more details, see "configuration parameters — ADBM — External database parameters").
- Starting with ADBM 1.7.3, you need to create users in the external database and grant them permissions manually. For more details, see Configure an external database for ADBM.

Concepts

ADBM implements **point-in-time recovery (PITR)** – the ability to restore databases to the selected point in time. This approach is based on several concepts, which are summarized below.

Backup

Backup is a consistent copy of an ADB cluster that can be used to restore databases in case of hardware and other failures. ADBM supports the following backup types:

- **Full**. When a full backup is created, the entire database content is backed up. The first backup running in ADBM within each timeline always has the full type, even if according to the schedule (or user choice – when launching a backup manually) the first should be a differential or incremental backup. A full backup can be used to restore data directly as it does not depend on any external files from other backups. The advantage of full backups is that all files are quickly restored (compared to other types). However, it is not recommended to create full backups regularly (hourly or daily) as they take a lot of time to be generated and occupy significant disk space.
- **Differential**. A differential backup contains only those database files that have changed since the last full backup was launched. In comparison with full backups, differential backups are faster and require less disk space. However, to restore data from a backup of this type, it is necessary to copy both its contents and files from the last full backup.
- **Incremental**. An incremental backup contains only those database files that have changed since the last backup of any other type was launched (full, differential, or incremental). Of all types, incremental backups are the fastest and occupy minimal disk space. However, their restoring takes longer because it is necessary to extract files from the last full and, if available, differential backup, and then apply all incremental backups sequentially.

WAL

Write-ahead log (WAL) is a standard mechanism to ensure that no committed changes are lost. All changes to data files (that contain tables, indexes, etc.) are written sequentially to the WAL. Afterwards, a background process writes the changes into the main database cluster files. In case of failures, the WAL can be replayed to make the database consistent.

WAL is broken up into individual 64 MB files called **segments**. Every record in a segment has a 16-digit logical sequence number (LSN) that is used to find this record by offset in the current segment file. A segment name, in turn, consists of the timeline number and LSN of the first segment record.

Using WAL significantly reduces the number of disk writes since there is no need to flush data pages to disk on every transaction commit. Only WAL files should be flushed to disk to guarantee that a transaction is committed.

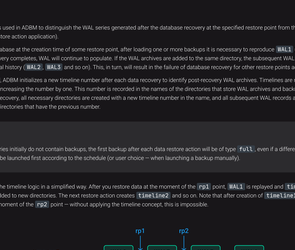
WAL plays a central role in the mechanism of point-in-time recovery (PITR) that is used in ADBM. By archiving the WAL data, ADBM allows you to restore databases at moment of any restore point covered by the available WAL data. In fact, the restore process requires two steps:

- Install a prior backup (or backups).
- Replay the WAL records, written after this backup, up to the specified named point.

Restore point

Restore point means a named recovery point, which is the minimum unit of data consistency granularity in ADB clusters. After a restore point is created (on a schedule or manually), you can restore the database state at the moment of the point creation. For each existing restore point, ADBM stores information on which backups should be used and which WAL segments should be reproduced to return the database state at the creation time of this point.

To better understand the mechanism of restore points, look at the figure below.



Example with restore points and different backup types

The following table explains which backups and WAL files will be used if you select any of the shown restore points when running the restore action.

Logic of restore points

Selected restore point	Objects to be used for recovery
rp1	full1, WAL1
rp2	full1, diff1, incr1, incr2, WAL2
rp3	full1, diff2, incr3, incr4, WAL3

Timeline

Timeline is a mechanism that is used in ADBM to distinguish the WAL series generated after the database recovery at the specified restore point from those created in the original database history (before the restore action application).

Suppose that to recover the database at the creation time of some restore point, after loading one or more backups it is necessary to reproduce `WAL1` (the number is used to simplify). After the archive recovery completes, WAL will continue to populate. If the WAL archives are added to the same directory, the subsequent WAL records will overwrite those that exist in the database original history (`WAL2`, `WAL3` and so on). This, in turn, will result in the failure of database recovery for other restore points added before recovery.

To avoid the conflicts described, ADBM initializes a new timeline number after each data recovery to identify post-recovery WAL archives. Timelines are numbered starting with `0`, with each successful restore action increasing the number by one. This number is recorded in the names of the directories that store WAL archives and backups divided by segments (so called **stanza**). With each data recovery, all necessary directories are created with a new timeline number in the name, and all subsequent WAL records are placed into new directories without overwriting files in the directories that have the previous number.

IMPORTANT

Since newly created directories initially do not contain backups, the first backup after each data restore action will be of type `full`, even if a differential or incremental backup should be launched first according to the schedule (or user choice – when launching a backup manually).

The following figure illustrates the timeline logic in a simplified way. After you restore data at the moment of the `rp1` point, `WAL1` is replayed and `timeline1` is created. Subsequent WAL records are added to new directories. The next restore action creates `timeline2` and so on. Note that after creation of `timeline1` and `timeline2` it is still possible to restore data at the moment of the `rp2` point — without applying the timeline concept, this is impossible.

Timeline logic

Quick start

The typical sequence of actions when working with ADBM via the web interface includes the following steps:

1. Connect to ADBM.
2. Create a configuration, which will be used to create backups and perform other related actions.
3. Run a backup manually or wait for the automatic backup launch on a schedule. If necessary — view a list of backups.
4. Create a restore point manually or wait for the automatic restore point creation on a schedule.
5. Run the auxiliary operations if necessary:
   - Cleanup backups
   - Verify backups
   - Terminate the running backup/cleanup action
   - Resume the latest terminated backup
6. Restore data from a backup if it is necessary to return the database state at the moment of one of existing restore points.

On each of the steps, you can view the details of running actions, including causes of the failures (if they are fixed).

Configure an external database for ADBM

Daria Barysheva

To Table of Contents

For production environments, it is recommended to use an external PostgreSQL database as ADBM data storage for high performance and fault tolerance. Starting with ADBM 1.7.3, to configure an external database, you need to follow the steps that are described below:

1. Perform the following queries in PostgreSQL. The queries should be run under the default user `postgres` with the `superuser` rights:

```
CREATE ROLE <user_name> LOGIN PASSWORD '<user_password>'; (1)
ALTER ROLE <user_name> SET search_path TO public, adbm;
CREATE DATABASE <database_name> WITH owner <user_name>; (2)
```

(1) Create the `<user_name>` user with appropriate rights for connecting to the external database.

(2) Create the `<database_name>` database for ADBM data migration.

2. Connect to the created database `<database_name>` under a superuser and run:

```
CREATE SCHEMA adbm; (1)
GRANT USAGE, CREATE ON SCHEMA adbm TO <user_name>; (2)
ALTER DEFAULT PRIVILEGES IN SCHEMA adbm GRANT UPDATE, INSERT, SELECT, DELETE ON TABLES TO <user_name>;
CREATE EXTENSION btree_gin WITH schema adbm;
CREATE EXTENSION pg_trgm WITH schema adbm;
GRANT SELECT ON pg_extension TO <user_name>;
```

(1) Create the `adbm` schema in the `<database_name>` database for ADBM data migration.

(2) Create extensions in the `adbm` schema and grant of their usage to the `<user_name>` user.

If you can assign superuser rights to a PostgreSQL user (which will be used for connecting to an external database from ADBM), it is enough to create a role and a database in PostgreSQL before installation or reconfiguration of ADBM:

```
CREATE ROLE <user_name> LOGIN PASSWORD '<user_password>' SUPERUSER;
ALTER ROLE <user_name> SET search_path TO public, adbm;
CREATE DATABASE <database_name> WITH owner <user_name>;
```

3. Provide the ADBM access to the external PostgreSQL database by adding the following record to the *pg_hba.conf* file on the PostgreSQL server.

Without SSL

```
host    <database_name>  <user_name>       <adbm_address>      trust
```

where:

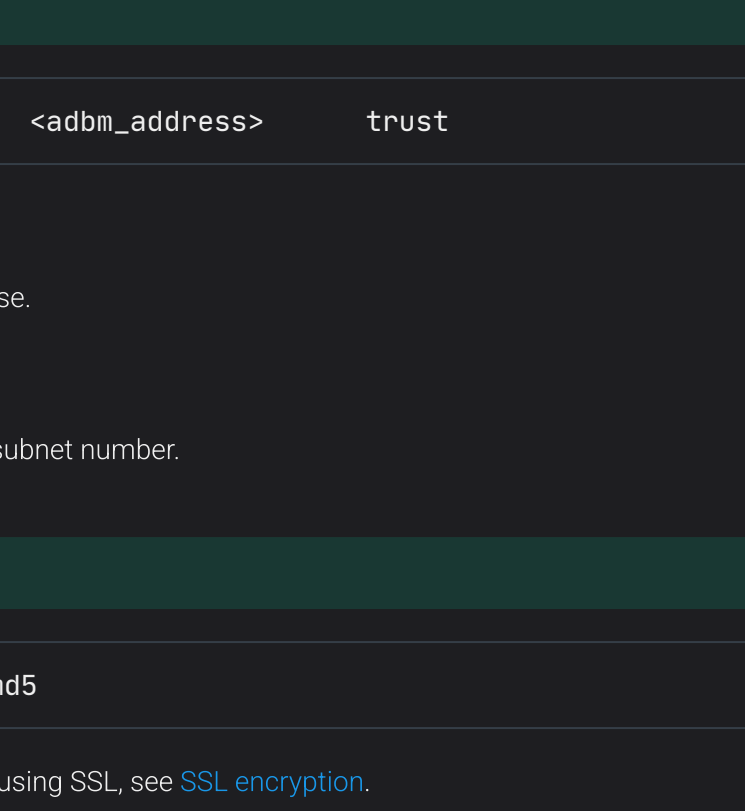
- `<database_name>` — a name of the created database.
- `<user_name>` — a name of the created user.
- `<adbm_address>` — an IP address of ADBM with a subnet number.

With SSL

```
hostssl    all  all       0.0.0.0/0      md5
```

For more information on how to configure PostgreSQL for using SSL, see SSL encryption.

4. On the ADBM service configuration page, activate the ***External database parameters*** toggle and fill in all parameters in the list that opens. The assignment of parameters is described in the Configuration parameters → ADBM → External database parameters section.



Parameters for connecting to the external PostgreSQL DB

5. Click ***Save*** to save the ADBM configuration.

6. Install the ADBM service using the Install service action or apply the ***Reconfigure & Restart*** action to the ADBM service if it is already installed.

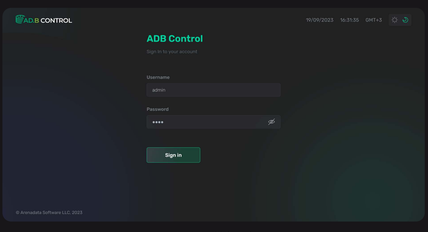
Connect to ADBM

Daria Barysheva

To Table of Contents

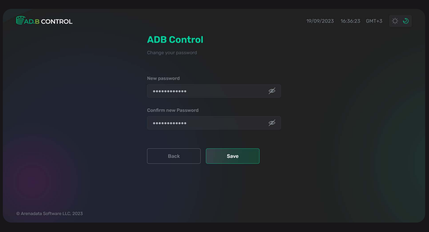
Currently, you can work with ADBM via the Arenadata DB Control (ADB Control) web interface. To connect to ADBM, follow the steps:

1. In the browser bar, enter the IP address of the host where ADB Control is deployed. To specify the port number, use the value of the Listening port parameter from the ***UI component parameters*** section defined when configuring the ADB Control service during the ADB cluster installation (`81` by default).
2. In the window that opens, enter the default user credentials and click ***Sign in***:
   - ***Username:*** admin
   - ***Password:*** 1234



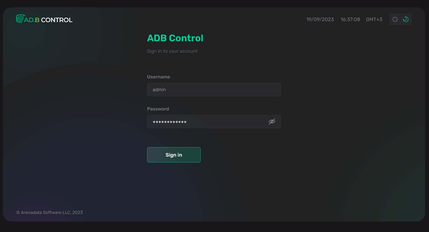
Log in to ADB Control

3. When you first log in, you should change a password for the `admin` user. Enter a new password in the ***New password*** field and confirm it in the ***Confirm new Password*** field. Click ***Save***. Note that your password must be greater than or equal to 12 characters by default. Any characters other than spaces are allowed to enter.



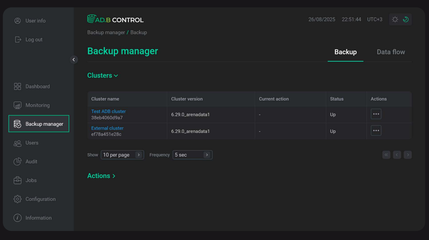
Change a password

4. After saving a password, re-enter your login and a new password. Note that when a certain number of unsuccessful login attempts is reached, the user will be blocked — permanently or temporarily, depending on the settings.



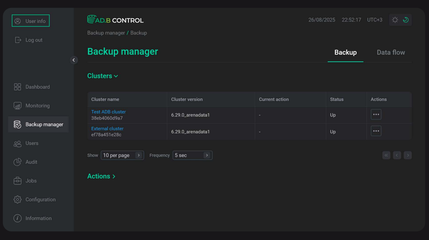
Log in to ADB Control with a new password

5. On the next page, select the ***Backup manager*** item in the left navigation menu.



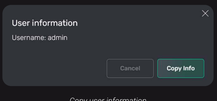
The "Backup manager" page

6. If you later need to get information about the current user, select the ***User info*** tab in the left navigation menu.



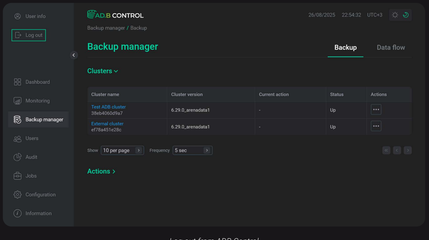
View user information

The modal window that opens displays the current user name, which can be copied by clicking ***Copy info***.



Copy user information

7. To log out from ADB Control, click ***Log out*** in the left navigation menu.



Log out from ADB Control

- All actions described in the subsequent sections of the ADBM documentation are performed on the ***Backup manager*** page via the ADB Control UI.
- The ***Backup manager*** page is available to users with the `Administrator`, `ADBM Administrator`, or `Owner` role.
- To get information on how to add new users and configure access rights for them, refer to the following articles:
  - Basic authentication
  - LDAP authentication
  - Authorization
- You can change security policies (password length limits, authorization attempt limit, blocking rules) on the ***Configuration → Security*** page. For more information, see Configure security policies.

Manage configurations in ADBM

Backup configuration

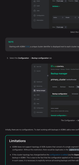
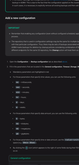
Overview

A backup configuration defines which databases will be backed up, how they will be backed up, and where the backup files will be stored. Backup configurations are created and managed on the Backups page. To open the Backups page, click **Configuration** > **Backup configuration**. To open the Add new configuration page, click **Add**.

1. Add a new backup configuration.



2. Edit an existing backup configuration.

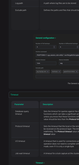


Add

Add a new backup configuration.

1. Go to **Configuration** > **Backup configuration** > **Add**.

2. Enter the **Name** of the backup configuration and select the schedule to use.



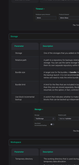
After the first run of Schedule 1, it will be running at 2:00 AM on the 1st of every month.

Limitations

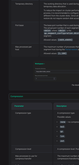
- Within one type of storage, it has access to only one storage. For example, if you have two Azure storage, you can only choose one of them.
- Within one backup configuration, it has access to only one storage. For example, if you have two Azure storage, you can only choose one of them.
- Within one backup configuration, it has access to only one schedule. For example, if you have two schedules, you can only choose one of them.

Add a new configuration

1. Go to **Configuration** > **Backup configuration** > **Add**.
2. Enter the **Backup configuration name**, select the **Schedule**, **Storage**, **Retention**, and **Databases** to be backed up.



3. Choose a schedule from the drop-down list, you can do the following:
   - Select a schedule.
   - Add a schedule.
   - Edit a schedule.
   - Delete a schedule.
4. Choose a storage from the drop-down list, you can do the following:
   - Select a storage.
   - Add a storage.
   - Edit a storage.
   - Delete a storage.
5. Choose the databases you want to back up. Click the **SELECT DATABASES** button to open the **Select databases** page. Click **OK** after you have made your selection.



6. Click **Save**.

Edit a configuration

1. Go to **Configuration** > **Backup configuration** > **Edit** (pencil icon).
2. Edit the configuration as needed.
3. Click **Save**.

Edit multiple jobs

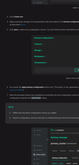
1. Go to **Configuration** > **Backup configuration** > **Edit multiple jobs**.
2. Select the backup configurations you want to edit.
3. Click **Edit**.
4. Edit the configuration as needed.
5. Click **Save**.

Schedule

Overview

Schedules are used to automate backups. Schedules are created and managed on the Schedules page. To open the Schedules page, click **Configuration** > **Schedules**. To open the Add new schedule page, click **Add**.

1. Add a new schedule.

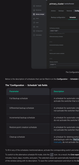


2. Edit an existing schedule.

Add

Add a new schedule.

1. Go to **Configuration** > **Schedules** > **Add**.



2. Enter the **Name** of the schedule.

3. Choose a backup configuration from the drop-down list, you can do the following:
   - Select a backup configuration.
   - Add a backup configuration.
   - Edit a backup configuration.
   - Delete a backup configuration.
4. Choose the **Frequency** you want to run the backup configuration.

5. Choose the **Time** you want to run the backup configuration.

6. Click **Save**.

Edit a configuration

1. Go to **Configuration** > **Schedules** > **Edit** (pencil icon).
2. Edit the schedule as needed.
3. Click **Save**.

Edit

Edit a schedule configuration.

1. Go to **Configuration** > **Schedules** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple schedules at the same time.

1. Go to **Configuration** > **Schedules** > **Edit multiple jobs**.
2. Select the schedules you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a configuration

1. Go to **Configuration** > **Schedules** > **Add**.

2. Enter a **Name** for the schedule.

3. Click **Add** in the **Backup configuration** section.

4. Enter a **Backup configuration name**, select the **Storage**, **Retention**, and **Databases** to be backed up.

5. Choose a storage from the drop-down list, you can do the following:
   - Select a storage.
   - Add a storage.
   - Edit a storage.
   - Delete a storage.
6. Choose the databases you want to back up. Click the **SELECT DATABASES** button to open the **Select databases** page. Click **OK** after you have made your selection.

7. Click **Save**.

Edit a configuration

1. Go to **Configuration** > **Schedules** > **Edit** (pencil icon).
2. Edit the configuration as needed.
3. Click **Save**.

Edit

Edit a schedule configuration.

1. Go to **Configuration** > **Schedules** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple schedules at the same time.

1. Go to **Configuration** > **Schedules** > **Edit multiple jobs**.
2. Select the schedules you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a configuration

1. Go to **Configuration** > **Schedules** > **Add**.

2. Enter a **Name** for the schedule.

3. Click **Add** in the **Backup configuration** section.

4. Enter a **Backup configuration name**, select the **Storage**, **Retention**, and **Databases** to be backed up.

5. Choose a storage from the drop-down list, you can do the following:
   - Select a storage.
   - Add a storage.
   - Edit a storage.
   - Delete a storage.
6. Choose the databases you want to back up. Click the **SELECT DATABASES** button to open the **Select databases** page. Click **OK** after you have made your selection.

7. Click **Save**.

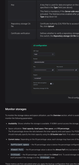
Edit a configuration

1. Go to **Configuration** > **Schedules** > **Edit** (pencil icon).
2. Edit the configuration as needed.
3. Click **Save**.

Edit

Edit a schedule configuration.

1. Go to **Configuration** > **Schedules** > **Edit** (pencil icon).



2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple schedules at the same time.

1. Go to **Configuration** > **Schedules** > **Edit multiple jobs**.
2. Select the schedules you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Storage

Overview

Storage is used to store backup files. Storage is created and managed on the Storage page. To open the Storage page, click **Configuration** > **Storage**. To open the Add new storage page, click **Add**.

1. Add a new storage.

2. Edit an existing storage.

Add a new storage

1. Go to **Configuration** > **Storage** > **Add** (plus sign).

2. Enter a **Name** for the storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Azure Blob Storage** connection string.

5. Click **Save**.

Edit a storage

1. Go to **Configuration** > **Storage** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple storages at the same time.

1. Go to **Configuration** > **Storage** > **Edit multiple jobs**.
2. Select the storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new storage

1. Go to **Configuration** > **Storage** > **Add**.

2. Enter a **Name** for the storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Amazon S3** connection string.

5. Click **Save**.

Edit a storage

1. Go to **Configuration** > **Storage** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple storages at the same time.

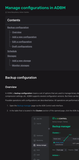
1. Go to **Configuration** > **Storage** > **Edit multiple jobs**.
2. Select the storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new storage

1. Go to **Configuration** > **Storage** > **Add**.

2. Enter a **Name** for the storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.



4. Enter the **Google Cloud Storage** connection string.

5. Click **Save**.

Edit a storage

1. Go to **Configuration** > **Storage** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple storages at the same time.

1. Go to **Configuration** > **Storage** > **Edit multiple jobs**.
2. Select the storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new storage

1. Go to **Configuration** > **Storage** > **Add**.

2. Enter a **Name** for the storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Google Cloud Storage** connection string.

5. Click **Save**.

Edit a storage

1. Go to **Configuration** > **Storage** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple storages at the same time.

1. Go to **Configuration** > **Storage** > **Edit multiple jobs**.
2. Select the storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new storage

1. Go to **Configuration** > **Storage** > **Add**.

2. Enter a **Name** for the storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Amazon S3** connection string.

5. Click **Save**.

Edit a storage

1. Go to **Configuration** > **Storage** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple storages at the same time.

1. Go to **Configuration** > **Storage** > **Edit multiple jobs**.
2. Select the storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new storage

1. Go to **Configuration** > **Storage** > **Add**.

2. Enter a **Name** for the storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Google Cloud Storage** connection string.

5. Click **Save**.

Edit a storage

1. Go to **Configuration** > **Storage** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple jobs

Edit multiple storages at the same time.

1. Go to **Configuration** > **Storage** > **Edit multiple jobs**.
2. Select the storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Monitor storages

Monitor storages are created and managed on the **Monitor** page. To open the Monitor page, click **Monitor**. To open the Add new monitor page, click **Add**.

1. Add a new monitor storage.

2. Edit an existing monitor storage.

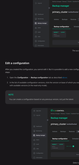
Add a new monitor storage

1. Go to **Monitor** > **Monitor storages** > **Add** (plus sign).

2. Enter a **Name** for the monitor storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Azure Blob Storage** connection string.



5. Click **Save**.

Edit a monitor storage

1. Go to **Monitor** > **Monitor storages** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple monitor storages

Edit multiple monitor storages at the same time.

1. Go to **Monitor** > **Monitor storages** > **Edit multiple jobs**.
2. Select the monitor storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new monitor storage

1. Go to **Monitor** > **Monitor storages** > **Add**.

2. Enter a **Name** for the monitor storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Amazon S3** connection string.

5. Click **Save**.

Edit a monitor storage

1. Go to **Monitor** > **Monitor storages** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple monitor storages

Edit multiple monitor storages at the same time.

1. Go to **Monitor** > **Monitor storages** > **Edit multiple jobs**.
2. Select the monitor storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new monitor storage

1. Go to **Monitor** > **Monitor storages** > **Add**.

2. Enter a **Name** for the monitor storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Google Cloud Storage** connection string.

5. Click **Save**.

Edit a monitor storage

1. Go to **Monitor** > **Monitor storages** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple monitor storages

Edit multiple monitor storages at the same time.

1. Go to **Monitor** > **Monitor storages** > **Edit multiple jobs**.
2. Select the monitor storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new monitor storage

1. Go to **Monitor** > **Monitor storages** > **Add**.

2. Enter a **Name** for the monitor storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Google Cloud Storage** connection string.

5. Click **Save**.

Edit a monitor storage

1. Go to **Monitor** > **Monitor storages** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple monitor storages

Edit multiple monitor storages at the same time.

1. Go to **Monitor** > **Monitor storages** > **Edit multiple jobs**.
2. Select the monitor storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new monitor storage

1. Go to **Monitor** > **Monitor storages** > **Add**.

2. Enter a **Name** for the monitor storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Amazon S3** connection string.

5. Click **Save**.

Edit a monitor storage

1. Go to **Monitor** > **Monitor storages** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple monitor storages

Edit multiple monitor storages at the same time.

1. Go to **Monitor** > **Monitor storages** > **Edit multiple jobs**.
2. Select the monitor storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Add a new monitor storage

1. Go to **Monitor** > **Monitor storages** > **Add**.

2. Enter a **Name** for the monitor storage.

3. Select a **Storage type** from the drop-down list, you can do the following:
   - Select a storage type.
   - Add a storage type.
   - Edit a storage type.
   - Delete a storage type.

4. Enter the **Google Cloud Storage** connection string.

5. Click **Save**.

Edit a monitor storage

1. Go to **Monitor** > **Monitor storages** > **Edit** (pencil icon).

2. Edit as needed.
3. Click **Save**.

Edit multiple monitor storages

Edit multiple monitor storages at the same time.

1. Go to **Monitor** > **Monitor storages** > **Edit multiple jobs**.
2. Select the monitor storages you want to edit.
3. Click **Edit**.
4. Edit as needed.
5. Click **Save**.

Run actions in ADAM

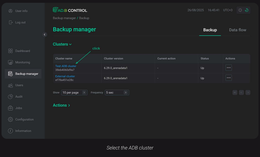
List of backups
Backup details

List of backups

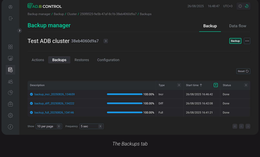
Regardless of how backups are created (manually or on a schedule), all of them are displayed on the ***Backups*** tab. To open this tab, follow the steps:

1. Open the Backup manager page via the ADB Control web interface.
2. In the table that is located in the **Clusters** section of the opened page, click the ADB cluster name.



Select the ADB cluster

3. Select the ***Backups*** tab.



The Backups tab

On the page that opens, there is a table with the following information on backups.

Backup list fields

Field	Description
Description	A backup name. Filled in automatically when performing a backup according to the `backup_<type>_<start_date>_<start_time>` template, where: • `<type>` – backup type (see ***Type*** below); • `<start_date>` – backup start date in the `YYYYMMDD` format; • `<start_time>` – backup start time in the `HHmmss` format. Starting with ADBM 2.4.0, there is a progress bar next to a backup name, which displays the backup execution progress (as a percentage of the estimated duration for all cluster segments). Note that backup progress is calculated only for the physical cluster reservation and does not include other actions
Type	The initial backup type (which was selected when creating a backup). *Possible values:* • `Full` – full backup; • `Diff` – differential backup; • `Incr` – incremental backup.
Start time	A backup start timestamp in the `DD/MM/YYYY HH:mm:ss` format
Status	A backup status. *Possible values:* • `Init` – the backup is being initialized. • `Running` – the backup is running. • `Terminating` – the backup is being terminated. • `Invalid` – after verification, the backup is considered incorrect. Such backups will be automatically dropped when the next cleanup procedure starts. • `Stopped` – the backup launch is stopped (after successful termination). • `Resume` – the backup is being resumed. • `Failed` – the backup launch is failed. • `Done` – the backup launch is successful. • `Unknown` – a repository that is specified in the backup configuration is inaccessible. For more information on possible transitions between statuses, see the diagram below

Backup statuses

In the column headers of the table with a list of backups, there are filters that you can use to select specific data. To open a filter, click the ⋮ icon. For those columns where the set of possible values is limited (e.g. ***Type***), you can select a value from the drop-down list. For columns that show date and time (e.g. ***Start time***), the time range can be selected from the calendar.

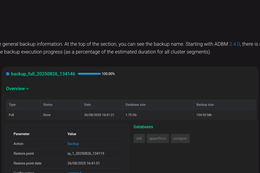
The ⋮ icon means that a filter is defined for the column. To reset all filters, click ***Reset***.

IMPORTANT

By default, the table on the ***Backups*** tabs shows the current-day backups. To view all backups, use the time filters.

Backup details

To view the backup details, click the backup description (***Description***) in the table on the ***Backups*** tab.

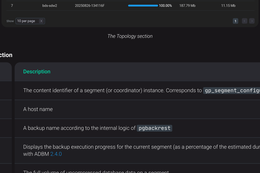


Select a backup

The next page contains the following sections:

- **Overview**
- **Topology**
- **Statuses**

The **Overview** section shows the general backup information. At the top of the section, you can see the backup name. Starting with ADBM 2.4.0, there is a progress bar next to the backup name, which displays the backup execution progress (as a percentage of the estimated duration for all cluster segments).

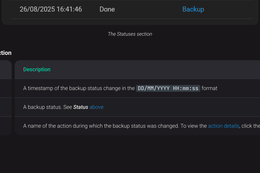


The Overview section

Fields of the Overview section

Field	Description
Type	A backup type. See ***Type*** above
Status	A backup status. See ***Status*** above
Date	A backup start timestamp in the `DD/MM/YYYY HH:mm:ss` format
Database size	The total volume of data files that have been backed up
Backup size	The total backup volume
Action	A name of the action within which the current backup was launched. You can click the name to view the detailed action information
Restore point	A name of the restore point created after the backup was completed
Restore point date	The restore point creation timestamp in the `DD/MM/YYYY HH:mm:ss` format
Configuration	A backup configuration version. To see the configuration details, click the version number
Flags	The flags that are selected for the backup operation (see ***Delta*** in the Backup description)
Databases	A list of databases that were in the DBMS at the time of the backup generation

The **Topology** section contains the backup topology information.



The Topology section

Fields of the Topology section

Field	Description
Segment	The content identifier of a segment (or coordinator) instance. Corresponds to `gp_segment_configuration.content`
Host	A host name
Label	A backup name according to the internal logic of `pgbackrest`
Progress	Displays the backup execution progress for the current segment (as a percentage of the estimated duration). Available starting with ADBM 2.4.0
Database size	The full volume of uncompressed database data on a segment
Backup size	The full volume of compressed database data on a segment

The **Statuses** section displays a history of changing the backup status.

The Statuses section

Fields of the Statuses section

Field	Description
Date	A timestamp of the backup status change in the `DD/MM/YYYY HH:mm:ss` format
Status	A backup status. See ***Status*** above
Action	A name of the action during which the backup status was changed. To view the action details, click the name

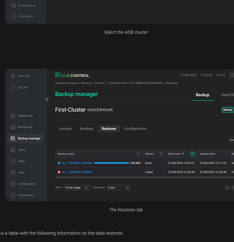
List of restores
Restore details

List of restores

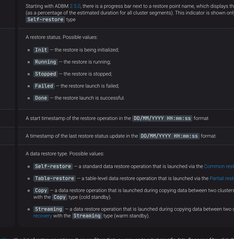
All restore operations that are launched by users in ADBM (via the Common restore, Partial restore actions or Disaster recovery) are displayed on the **Restores** tab. To open this tab, follow the steps:

1. Open the Backup manager page via the ADB Control web interface.
2. In the table that is located in the **Clusters** section of the opened page, click the ADB cluster name.



Select the ADB cluster

3. Select the **Restores** tab.



The Restores tab

On the page that opens, there is a table with the following information on the data restores.

Restore list fields

Field	Description
Restore point	A restore point that was selected to restore data. Starting with ADBM 2.4.0, there is a progress bar next to a restore point name, which displays the restore execution progress (as a percentage of the estimated duration for all cluster segments). This indicator is shown only for data restores with the `Self-restore` type
Status	A restore status. Possible values: • `Init` – the restore is being initialized; • `Running` – the restore is running; • `Stopped` – the restore is stopped; • `Failed` – the restore launch is failed; • `Done` – the restore launch is successful.
Start time	A start timestamp of the restore operation in the `DD/MM/YYYY HH:mm:ss` format
Update time	A timestamp of the last restore status update in the `DD/MM/YYYY HH:mm:ss` format
Restore type	A data restore type. Possible values: • `Self-restore` – a standard data restore operation that is launched via the Common restore action; • `Table-restore` – a table-level data restore operation that is launched via the Partial restore action; • `Copy` – a data restore operation that is launched during copying data between two clusters as a part of Disaster recovery with the `Copy` type (cold standby); • `Streaming` – a data restore operation that is launched during copying data between two clusters as a part of Disaster recovery with the `Streaming` type (warm standby).

In the column headers of the table with a list of restore operations, there are filters that you can use to select specific data. To open a filter, click the ⋮ icon. For those columns where the set of possible values is limited (e.g. **Status**), you can select a value from the drop-down list. For some columns (e.g. **Restore point**), the search value should be entered. For columns that show date and time (e.g. **Start time**), the time range can be selected from the calendar.

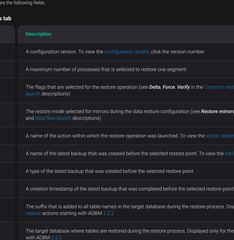
The ▼ icon means that a filter is defined for the column. To reset all filters, click **Reset**.

IMPORTANT

By default, the table on the **Restores** tab shows the current-day restore operations. To view all restores, use the time filters.

Restore details

To view the restore details, click the restore point name (**Restore point**) in the table on the **Restores** tab.



Select a restore operation

The next page displays the following information:

- The table with general restore information.
- The **Parameters** tab with additional information on parameters.
- The **Tables** tab with information on the restored tables.
- The **Topology** section with information on the cluster topology information.

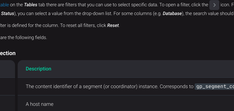
NOTE

- The **Tables** tab is displayed only for the Partial restore actions starting with ADBM 2.2.0.
- The **Topology** section is displayed starting with ADBM 2.9.0.

In the table, there are the following fields.

Fields of the table

Field	Description
Status	A restore status. See **Status** above
Restore type	A data restore type. See **Restore type** above
Start time	A start timestamp of the restore operation in the `DD/MM/YYYY HH:mm:ss` format
Update time	A timestamp of the last restore status update in the `DD/MM/YYYY HH:mm:ss` format



Restore details: general table

On the **Parameters** tab, there are the following fields.

Fields of the Parameters tab

Field	Description
Configuration	A configuration version. To view the configuration details, click the version number
Processes	A maximum number of processes that is selected to restore one segment
Flags	The flags that are selected for the restore operation (see **Delta**, **Force**, **Verify** in the Common restore action and data flow launch descriptions)
Mirrors restore mode	The restore mode selected for mirrors during the data restore configuration (see **Restore mirrors** in the Common restore action and data flow launch descriptions)
Action	A name of the action within which the restore operation was launched. To view the action details, click the name
Backup	A name of the latest backup that was created before the selected restore point. To view the backup details, click the name
Type	A type of the latest backup that was created before the selected restore point
Date	A creation timestamp of the latest backup that was completed before the selected restore point
Table suffix	The suffix that is added to all table names in the target database during the restore process. Displayed only for the Partial restore actions starting with ADBM 2.2.0
Target database	The target database where tables are restored during the restore process. Displayed only for the Partial restore actions starting with ADBM 2.2.0
Databases	A list of source databases selected for the data restore (from their backups)

Restore details: Parameters

On the **Tables** tab, there are the following fields.

Fields of the Tables tab

Field	Description
Database	A name of the target database where the selected table is restored
Schema	A name of the target schema where the selected table is restored
Table name	A name of the restored table (after the restore operation)
Status	A table restore status. See **Status** above

TIP

If you click the ⋯ icon in the **Database** column, you can see the original names of the database, schema, and table from which the table data was restored – in the new row that appears.

Restore details: Tables

In the column headers of the table on the **Tables** tab there are filters that you can use to select specific data. To open a filter, click the ⋮ icon. For those columns where the set of possible values is limited (e.g. **Status**), you can select a value from the drop-down list. For some columns (e.g. **Database**), the search value should be entered.

The ▼ icon means that a filter is defined for the column. To reset all filters, click **Reset**.

Fields of the Topology section

Field	Description
Segment	The content identifier of a segment (or coordinator) instance. Corresponds to `gp_segment_configuration.content`
Host	A host name
Progress	Displays the restore execution progress for the current segment (as a percentage of the estimated duration). Available starting with ADBM 2.9.0 for data restores with the `Self-restore` type

Restore details: Topology

Configuration

Shoutbar can be configured through environment variables, configuration files, and command-line flags. When the same setting is provided in more than one place, the most specific source wins: flags override environment variables, which override configuration files, which override built-in defaults.

Configuration files

Shoutbar looks for a configuration file in the following locations, in order:

1. `./shoutbar.toml`
2. `$XDG_CONFIG_HOME/shoutbar/shoutbar.toml`
3. `/etc/shoutbar/shoutbar.toml`

The first file found is used. Pass `--config <path>` to skip the search and load a specific file.

```toml
# shoutbar.toml
[server]
bind = "0.0.0.0:8080"
workers = 4

[storage]
data_dir = "/var/lib/shoutbar"
max_shouts = 100000

[log]
level = "info"
format = "text"
```

Environment variables

Every configuration key has a corresponding environment variable. Nested keys are joined with `__`, and the whole name is prefixed with `SHOUTBAR_`.

Variable	Default	Description
`SHOUTBAR_SERVER__BIND`	`127.0.0.1:8080`	Address and port to listen on
`SHOUTBAR_SERVER__WORKERS`	`2`	Number of worker threads
`SHOUTBAR_STORAGE__DATA_DIR`	`./data`	Directory for shout files
`SHOUTBAR_STORAGE__MAX_SHOUTS`	`10000`	Maximum shouts kept per channel
`SHOUTBAR_LOG__LEVEL`	`info`	Log level: `error`, `warn`, `info`, `debug`, `trace`
`SHOUTBAR_LOG__FORMAT`	`text`	Log format: `text` or `json`

Command-line flags

Run `shoutbar --help` to see the full list. The most commonly used flags are:

```
shoutbar [OPTIONS] <COMMAND>

Options:
  -c, --config <PATH>     Load configuration from this file
  -v, --verbose           Increase log verbosity (repeatable)
  -q, --quiet             Suppress all output except errors
      --data-dir <PATH>   Override storage.data_dir
      --bind <ADDR>       Override server.bind
```

Data model

Shouts

A shout is the basic unit of content. Each shout has a numeric id, a channel, a body, and a timestamp. Shouts are immutable once written; there is no edit operation.

```
Shout {
    id: u64,
    channel: String,
    body: String,
    created_at: Timestamp,
}
```

Channels

Channels are created implicitly the first time a shout is posted to them. Channel names must match `[a-z0-9_-]{1,32}`.

Users and sessions

Shoutbar does not have a built-in user database. Authentication is delegated to a reverse proxy, which passes the authenticated username in the `X-Shoutbar-User` header. If the header is absent, shouts are recorded as anonymous.

Command-line interface

Global flags

The global flags listed above apply to every subcommand.

Subcommands

```
shoutbar serve              Run the server in the foreground
shoutbar post <CHANNEL> <BODY>   Post a shout from the command line
shoutbar tail <CHANNEL>     Print new shouts as they arrive
shoutbar list               List channels and shout counts
shoutbar export <CHANNEL>   Export a channel to JSON
shoutbar import <FILE>      Import shouts from a JSON export
shoutbar migrate            Apply pending storage migrations
shoutbar check              Validate configuration and exit
```

Exit codes

Code	Meaning
`0`	Success
`1`	Generic error
`2`	Invalid command-line usage
`3`	Configuration error
`4`	Storage error
`5`	Network error

Configuration management

Layered configuration

Shoutbar builds its configuration by merging sources in a fixed order. Later sources override earlier ones, and only the keys that are actually set in a later source are touched.

Order	Source	Typical use
1	Built-in defaults	Sensible values for a single-user install
2	System file (`/etc/shoutbar/shoutbar.toml`)	Site-wide settings managed by the operator
3	User file (`$XDG_CONFIG_HOME/shoutbar/shoutbar.toml`)	Per-user overrides
4	Environment variables	Container and service-manager configuration
5	Command-line flags	One-off invocations

Validation

Validation runs after all sources have been merged. A configuration that fails validation is rejected and the server refuses to start; `shoutbar check` runs the same validation without starting anything.

Key	Rule
`server.bind`	Must parse as a socket address
`server.workers`	Must be between 1 and 256
`storage.data_dir`	Must be writable by the server user
`storage.max_shouts`	Must be at least 100
`log.level`	Must be one of `error`, `warn`, `info`, `debug`, `trace`
`log.format`	Must be one of `text`, `json`

Secrets

Secrets such as API tokens and session keys should never be written directly into a configuration file that is checked into version control. Shoutbar reads them from environment variables or from files referenced by `*_FILE` variables, which is the convention used by most container orchestrators.

```
SHOUTBAR_AUTH__SESSION_KEY_FILE=/run/secrets/shoutbar_session_key
```

Data files and storage

Layout on disk

Shoutbar stores everything under `storage.data_dir`. The layout is deliberately boring so that it can be inspected with ordinary tools.

```
/var/lib/shoutbar/
    shoutbar.db          SQLite database (shouts, channels, users)
    shoutbar.db-wal      Write-ahead log
    shoutbar.db-shm      Shared memory file
    backups/             Automatic backups
    exports/             Default destination for `shoutbar export`
```

Backups

Backups are taken automatically before any migration and on a schedule controlled by `storage.backup_interval`. They can also be triggered by hand.

```
shoutbar backup --to /var/backups/shoutbar-$(date +%F).db
```

Migrations

Schema changes are applied by `shoutbar migrate`. The server will refuse to start if the database is behind the binary, and will refuse to start if the database is ahead of the binary, so that a downgrade never silently corrupts data.

Networking

Listening addresses

Shoutbar can listen on a TCP address or on a Unix domain socket. Unix sockets are the recommended choice when a reverse proxy runs on the same machine.

```
server.bind = "127.0.0.1:8080"
server.bind = "unix:/run/shoutbar/shoutbar.sock"
```

Proxies and TLS

Shoutbar does not terminate TLS itself. Put it behind a reverse proxy that does, and set `server.trusted_proxies` to the proxy's address so that `X-Forwarded-For` is honored.

Timeouts

Key	Default	Description
`server.read_timeout`	`30s`	Maximum time to read a request
`server.write_timeout`	`30s`	Maximum time to write a response
`server.idle_timeout`	`120s`	Keep-alive connection lifetime

Logging and diagnostics

Log levels

Log levels are ordered from most to least verbose: `trace`, `debug`, `info`, `warn`, `error`. Setting a level includes all levels above it.

Structured logs

With `log.format = "json"` every log line is a single JSON object, suitable for ingestion by a log aggregator.

```
{"ts":"2026-04-12T09:14:02Z","level":"info","msg":"shout posted","channel":"general","id":4821}
```

Health checks

`GET /healthz` returns `200 OK` when the server is ready to accept traffic and `503` during startup and shutdown. `GET /metrics` exposes Prometheus-format counters.

Operations

Running as a service

A systemd unit file is provided in `contrib/shoutbar.service`. Install it, create a dedicated `shoutbar` user, and point `storage.data_dir` at a directory that user owns.

Upgrades

Upgrades are a stop, replace, migrate, start sequence. Because migrations are forward-only, take a backup first.

```
systemctl stop shoutbar
shoutbar backup --to /var/backups/shoutbar-pre-upgrade.db
install -m 0755 shoutbar /usr/local/bin/shoutbar
shoutbar migrate
systemctl start shoutbar
```

Troubleshooting

Symptom	Likely cause	Fix
Server refuses to start	Configuration error	Run `shoutbar check` and read the message
`database is locked`	Another process holds the WAL	Stop duplicate instances
Shouts appear anonymous	Proxy not trusted	Add the proxy to `server.trusted_proxies`
High memory use	`storage.max_shouts` too large	Lower the limit and run `shoutbar migrate`

View actions in ADBM

Dana Baryshova

Contents

To Table of Contents

List of actions

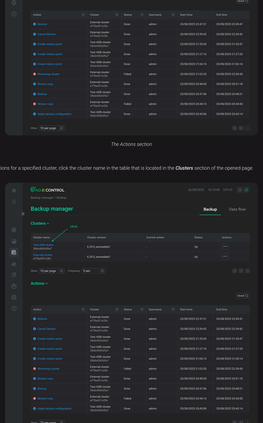
Action details

In ADBM, an **action** means any API call, SQL request, or internal procedure that starts when backup configurations or operations related to backups and DR are being applied. Each action can trigger several other related actions — **subactions**.

List of actions

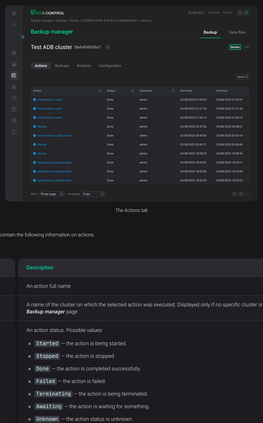
To view a list of actions, follow the steps:

1. Open the Backup manager page via the ADB Control web interface. The **Actions** section of the next page contains a table with general information on actions for all available ADB clusters.



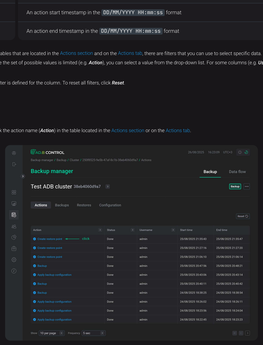
The Actions section

2. If you want to display actions for a specified cluster, click the cluster name in the table that is located in the **Clusters** section of the opened page.



Select the ADB cluster

The **Actions** tab of the opened page contains a table with general information on actions for the selected cluster.



The Actions tab

Both tables mentioned above contain the following information on actions.

Action list fields

Field	Description
Action	An action full name
Cluster	A name of the cluster on which the selected action was executed. Displayed only if no specific cluster is selected on the *Backup manager* page
Status	An action status. Possible values: • `Started` — the action is being started. • `Stopped` — the action is stopped. • `Done` — the action is completed successfully. • `Failed` — the action is failed. • `Terminating` — the action is being terminated. • `Awaiting` — the action is waiting for something. • `Unknown` — the action status is unknown. • `Warning` — something went wrong during the action, but it is not critical for the parent action flow.
Username	The user who performed the selected action
Start time	An action start timestamp in the `DD/MM/YYYY HH:mm:ss` format
End time	An action end timestamp in the `DD/MM/YYYY HH:mm:ss` format

In the column headers of the tables that are located in the Actions section and on the Actions tab, there are filters that you can use to select specific data. To open a filter, click the icon. For those columns where the set of possible values is limited (e.g. **Action**), you can select a value from the drop-down list. For some columns (e.g. **Username**), the search value should be entered.

The icon means that a filter is defined for the column. To reset all filters, click **Reset**.

Action details

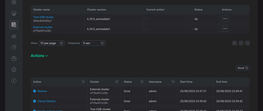
To view the action details, click the action name (**Action**) in the table located in the Actions section or on the Actions tab.

Select an action

The next page contains the following sections:

- **Overview**
- **Subactions**

The **Overview** section displays the action name, identifier, and general information.



The Overview section

Fields of the Overview section

Field	Description
Cluster	A cluster name (see **Cluster** above)
Submitted by	The user who submitted the selected action
Start time	An action start timestamp in the `DD/MM/YYYY HH:mm:ss` format
End time	An action end timestamp in the `DD/MM/YYYY HH:mm:ss` format
Status	An action status (see **Status** above)

The **Subactions** section displays a list of subactions that are triggered by the top-level action. All subactions are ordered by the start timestamp — from the first action to the last one. For each action in the list, the action name and status are displayed.

The Subactions section

When you click any subaction in the list, the detailed information on it is displayed in the right part of the screen.

Subaction details

Field	Description
Action name	A subaction name
Action ID	A subaction identifier
Action status	A subaction status (see **Status** above)
Start time	A subaction start timestamp in the `DD/MM/YYYY HH:mm:ss` format
End time	A subaction end timestamp in the `DD/MM/YYYY HH:mm:ss` format
Duration	A subaction duration in hours, minutes, and seconds

For some low-level actions, the **End Results** section with the subaction result can be displayed below the detailed information.

The End Results section

TIP

You can copy the result by clicking Copy in the top right corner of the code sample. This functionality can be useful for debugging errors.

ADB ClickHouse Connector overview

Daria Barysheva

To Table of Contents

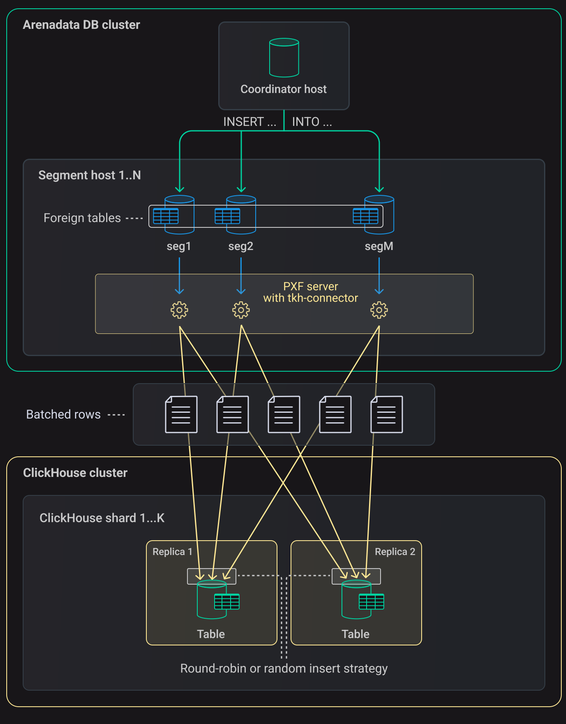
Unlike the previous version Tkhemali Connector 1.X based on the mechanism of external tables, ADB ClickHouse Connector is implemented on the basis of a foreign data wrapper and foreign tables. Consequently, the new version of the ADQM/ClickHouse connector has the following features:

- **More convenient and secure user management**. While in the previous connector version you had to write user credentials in the `LOCATION` option at the level of each external table or in a separate file explicitly, in ADB ClickHouse Connector the user login and password are stored in a separate ADB database object user mapping. It is enough to create a user mapping object once for one ClickHouse cluster with which you plan to connect. If necessary, the data can be modified later via the `ALTER USER MAPPING` command.
- **Multi-level connection settings**. General settings that will be the same for all or most ClickHouse target tables (load distribution strategy, need to use a staging layer, restrictions for batch data, and so on) can be specified at the server object level, and private settings (e.g. specific table name) — at the foreign table level. In the previous version of the connector, all settings had to be specified at the external table level.
- **New load balancing mechanism**. In the new connector version, the list of ClickHouse hosts (through which you plan to load data from ADB) is specified in the `hosts` option. The separate option `distribution_type` is used to declare the load distribution strategy. Two types of distribution are supported now: random and round-robin. The second method is preferable in terms of uniformity of load. At the same time, when writing to distributed tables, it is possible to specify the ClickHouse cluster name in the `cluster` option at the foreign table level. In this case, it is not necessary to define explicitly all hosts: one entry point is sufficient, and the full list of hosts will be automatically obtained from the cluster metadata. In the previous version of the connector, it was also possible to get a list of hosts for distributed tables, but the load on ClickHouse cluster hosts could be uneven.
- **Flexible management of custom settings**. Custom settings of connection and execution of queries to ClickHouse can now be defined in the `clickhouse_properties` option in the following format: `<custom_option>=<value>;[…]`. To change the settings, it is enough to execute the `ALTER SERVER` or the `ALTER FOREIGN TABLE` command. In the previous version of the connector, the custom settings for ClickHouse were stored in the XML file that needed to be copied to all ADB segment hosts.
- **More control over the resource release**. A foreign data wrapper supports "out of box" transactions and allows subscribing to transaction control hooks. Due to this, the new connector version provides more control over the progress of requests and resource release, which is especially relevant for transactional data loading via staging tables. In the previous version of the connector, a staging layer might not have been removed under certain circumstances and it was necessary to remove it manually.
- **Simple query syntax**. There is no need to use the `txn` function to enable a transaction mode (staging layer usage) anymore. In the new connector version for data transmission from ADB to ClickHouse, it is enough to execute the ordinary `INSERT` query against the corresponding foreign table. Staging tables are now managed by a separate flag `use_staging`. In addition, in the previous connector version, it was necessary to specify full names of staging tables when creating external tables. In ADB ClickHouse Connector, only the target table name in ClickHouse is required to be filled in the `resource` option at the foreign table level. Names for staging tables are automatically generated based on the template that is specified in the `staging_table_name_format` option.

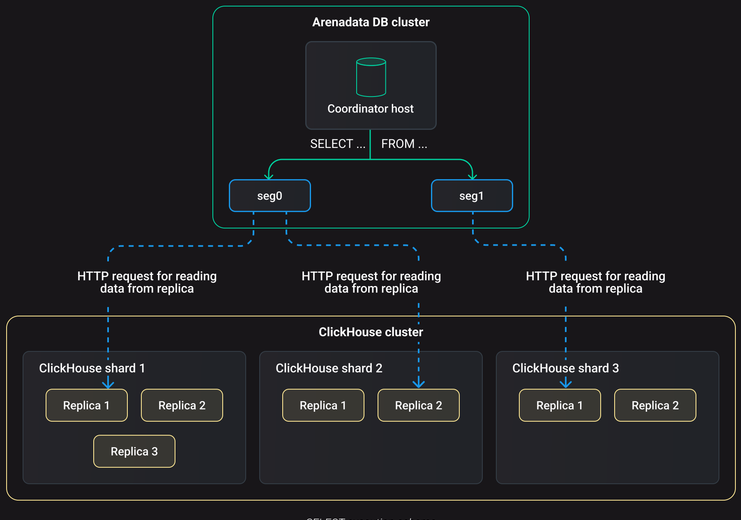
IMPORTANT

- ADB ClickHouse Connector is available in the Enterprise version of ADB:
  - In ADB 7 — starting with the 7.4.0 version.
  - In ADB 6 — starting with the 6.23.3.44 version.
- Starting with 6.24.3.47 in ADB 6 and 7.4.0 in ADB 7, ADB ClickHouse Connector supports both writing and reading data from ADQM/ClickHouse. However, to use a foreign table in ADB for reading, you should specify column names that match exactly the corresponding names in a source table in ADQM/ClickHouse.

The high-level architecture view of the new connector version is shown below.



INSERT execution schema



SELECT execution schema

ADB ClickHouse Connector installation

Daria Barysheva

To Table of Contents

To install ADB ClickHouse Connector, follow the steps:

1. Make sure that PXF and ADB ClickHouse Connector services are installed. For information on how to add services to ADB clusters, see Add services.
2. Add the new custom profile `Tkh_clickhouse:text` to the PXF configuration file */var/lib/pxf/conf/pxf-profiles.xml* on **coordinator**. To edit the file, you can use the `vi` or `vim` command:

```
$ sudo vi /var/lib/pxf/conf/pxf-profiles.xml
```

The content of the changed file can look as follows. In the given example, the file does not contain other profiles:

```
<profiles>
    <profile>
        <name>Tkh_clickhouse:text</name>
        <description>Clickhouse</description>
        <plugins>
            <accessor>io.arenadata.tkh.pxf.TkhFdwAccessor</accessor>
            <resolver>io.arenadata.tkh.pxf.TkhResolver</resolver>
        </plugins>
    </profile>
</profiles>
```

NOTE

The directory, where PXF configuration files are located, is defined by the `PXF_BASE` environment variable. The default value is */var/lib/pxf*. The path may differ in your environment.

3. Log in under the default user `gpadmin`. All the commands listed in the subsequent steps should be performed on **coordinator**:

```
$ sudo su - gpadmin
```

4. Synchronize the PXF configuration on all hosts in the ADB cluster:

```
$ pxf cluster sync
```

Result:

```
Syncing PXF configuration files from coordinator host to standby coordinator host and 2 segment hosts...
PXF configs synced successfully on 3 out of 3 hosts
```

5. Restart PXF:

```
$ pxf cluster restart
```

Result:

```
Restarting PXF on coordinator host, standby coordinator host, and 2 segment hosts...
PXF restarted successfully on 4 out of 4 hosts
```

6. Connect to the database via `psql` (or any other client program):

```
$ psql adb
```

7. To check that the new extensions `pxf_fdw` and `tkh_fdw` are available, use the `psql` meta-command `\dx`:

```
\dx
```

The output contains the `pxf_fdw` and `tkh_fdw` extensions:

```
                                    List of installed extensions
      Name        | Version |   Schema   |                            Description
------------------+---------+------------+-------------------------------------------------------------------
 adb_fdw          | 1.0     | public     | foreign-data wrapper for remote ADB servers
 arenadata_toolkit | 1.0     | public     | extension is used for manipulation of objects created by adb-bundle
 dblink           | 1.2     | public     | connect to other PostgreSQL databases from within a database
 gp_exttable_fdw  | 1.0     | pg_catalog | External Table Foreign Data Wrapper for Greengage
 gp_toolkit       | 1.8     | gp_toolkit | various GPDB administrative views/functions
 kadb_fdw         | 0.16    | kadb       | Kafka-ADB foreign data wrapper
 plpgsql          | 1.0     | pg_catalog | PL/pgSQL procedural language
 pxf              | 2.1     | public     | Extension which allows to access unmanaged data
 pxf_fdw          | 1.0     | public     | PXF Foreign Data Wrapper for Greengage
 tkh_fdw          | 1.0     | public     | ClickHouse Foreign Data Wrapper for Greenplum
(10 rows)
```

8. You can also check that the new foreign data wrapper `tkh_fdw` is available using the following SQL query against the `pg_catalog.pg_foreign_data_wrapper` system table:

```
SELECT * FROM pg_catalog.pg_foreign_data_wrapper;
```

Result:

```
  oid  |     fdwname     | fdwowner | fdwhandler | fdwvalidator | fdwacl |                                                    fdwoptions
-------+-----------------+----------+------------+--------------+--------+-----------------------------------------------------------------
-------------------------------------
 13702 | gp_exttable_fdw |       10 |      13700 |        13701 |        |
 17124 | dblink_fdw      |       10 |          0 |        17123 |        |
 17175 | adb_fdw         |       10 |      17173 |        17174 |        |
 17187 | jdbc_pxf_fdw    |       10 |      17185 |        17186 |        | {protocol=jdbc,"mpp_execute=all segments"}
 17188 | hdfs_pxf_fdw    |       10 |      17185 |        17186 |        | {protocol=hdfs,"mpp_execute=all segments"}
 17189 | hive_pxf_fdw    |       10 |      17185 |        17186 |        | {protocol=hive,"mpp_execute=all segments"}
 17190 | hbase_pxf_fdw   |       10 |      17185 |        17186 |        | {protocol=hbase,"mpp_execute=all segments"}
 17191 | s3_pxf_fdw      |       10 |      17185 |        17186 |        | {protocol=s3,"mpp_execute=all segments"}
 17192 | gs_pxf_fdw      |       10 |      17185 |        17186 |        | {protocol=gs,"mpp_execute=all segments"}
 17193 | adl_pxf_fdw     |       10 |      17185 |        17186 |        | {protocol=adl,"mpp_execute=all segments"}
 17194 | wasbs_pxf_fdw   |       10 |      17185 |        17186 |        | {protocol=wasbs,"mpp_execute=all segments"}
 17195 | file_pxf_fdw    |       10 |      17185 |        17186 |        | {protocol=file,"mpp_execute=all segments"}
 17201 | tkh_fdw         |       10 |      17200 |        17199 |        | {protocol=tkh_clickhouse,"mpp_execute=all
segments",format=text}
 17210 | kadb_fdw        |       10 |      17209 |        17211 |        | {"mpp_execute=all

(14 rows)
```

ADB ClickHouse Connector configuration

Denis Ryzhkov

Contents

To Table of Contents

Server
User mapping
Foreign table

To send data from ADB to ClickHouse via ADB ClickHouse Connector, you should first create the following objects on the ADB cluster side:

1. Server — encapsulates connection information that a foreign data wrapper uses to access an external data source.
2. User mapping — provides user authentication to an external data source.
3. Foreign table — a table in ADB that defines the remote data structure. A foreign table has no storage in ADB, but can be used in queries just like a normal table.

To see how to use the listed objects to send data from ADB to ADQM, refer to ADB ClickHouse Connector usage examples.

IMPORTANT

- For each ClickHouse cluster to which you plan to send queries from ADB, it is sufficient to create one server and one user mapping. However, there may be several foreign tables if you need to send queries against various ClickHouse tables.
- All options that are listed in the tables below (Server options, User mapping options, Foreign table options) should be defined in the text format (i.e. in single quotes `'`). The `Type` column in the tables shows what data type will be used when validating input values.

Server

To create a server, use the `CREATE SERVER` command. The basic command syntax is listed below:

```
CREATE SERVER <server_name> [ TYPE '<server_type>' ] [ VERSION '<server_version>' ]
  FOREIGN DATA WRAPPER <fdw_name>
  [ OPTIONS ( [ <option> '<value>' [, ... ] ] ) ]
```

where:

- `<server_name>` – a server name in ADB. Should be unique within the current ADB database.
- `<server_type>` – an optional server type.
- `<server_version>` – an optional server version.
- `<fdw_name>` – a foreign data wrapper name. You should use the `tkh_fdw` foreign data wrapper, which is automatically created after the connector installation (see step 8 in ADB ClickHouse Connector installation).
- `<option>` – server options that define the connection details. The options that are available for ADB ClickHouse Connector are listed in the Server options table. Note that these options can be defined both at the server level and at the foreign table level. Options marked as required should be specified at least in one definition (server or table). Table-level options take precedence.
- `<value>` – option values.

NOTE

- To create a server, you need the `USAGE` privilege on the `tkh_fdw` foreign data wrapper. The user who creates the server becomes its owner.
- The full description of the `CREATE SERVER` command syntax is available in the Greenplum documentation.
- To edit a server definition, use the ALTER SERVER command. To delete a server, use DROP SERVER.

Server options

Name	Type	Description	Default	Required
database	TEXT	A name of the ClickHouse database where the target table is located. Should match the following regular expression: `^[a-zA-Z_][0-9a-zA-Z_]*$`	–	Yes
hosts	TEXT	A list of ClickHouse hosts where the target table is located. A ClickHouse cluster does not have a single entry point (coordinator node), so the requests can be sent to any host in the cluster. To reduce the load, data batches are sent to hosts from the connector according to the `random` or the `round-robin` distribution strategy (see `distribution_type` below). Validation rules for the `hosts` option are listed below	–	Yes
lines_batch_size	INT	The maximum number of rows in the data batch sent to ClickHouse by the connector. Positive integers are allowed.	100000	No
bytes_batch_size_mb	INT	The maximum batch size of data sent to ClickHouse by the connector (in MB). If the `lines_batch_size` option is also defined, the `bytes_batch_size_mb` value will be used. Positive integers are allowed.	–	No
send_compressed	BOOL	The flag that indicates whether to use compression on the connector side before sending data to ClickHouse. Possible values: • `true` — use data compression. • `false` — do not use data compression.	false	No
send_delay	INT	A delay between connector requests to ClickHouse (in milliseconds). Positive integers are allowed.	300	No
insert_distributed_sync	BOOL	Enables or disables synchronous data load to distributed tables. Possible values: • `true` — data is inserted synchronously. The `INSERT` query is considered successful after all data is added to all shards (at least to one replica per shard if `internal_replication` = `true` in ClickHouse). • `false` — data is inserted asynchronously.	true	No
distribution_type	TEXT	Defines the strategy of load distribution between ClickHouse hosts (see `hosts` above) when performing data load operations from the connector side. Possible values: • `random` — hosts are selected randomly. • `round-robin` — hosts are selected based on the round-robin algorithm. This option value is preferable in terms of the uniform load distribution.	random	No
use_staging	BOOL	The flag that indicates whether to create staging tables in ClickHouse before inserting data into the target table. Used to emulate transactions that are not present in ClickHouse. Staging tables are supported only for the following ClickHouse engine families: MergeTree (including Replicated* engines) and Distributed. For other engines, an error will be returned, since not all engines support partitioning in ClickHouse. Possible values: • `true` — use staging tables. • `false` — do not use staging tables. In this mode, there are certain risks, as the consistency of data insertions can be disturbed. However, the mode is available for single insertions into empty target tables.	–	Yes if `use_staging` = `true`
staging_table_name_form at	TEXT	Defines the staging table name format (see `use_staging` above). Example: `'$tgt_$'`. The first placeholder (`$`) is replaced with the name of the target table in ClickHouse (see `resource` in Foreign table options). The second placeholder is replaced with the integer identifier that is automatically generated on the coordinator node of ADB	–	No
clickhouse_properties	TEXT	A list of ClickHouse custom options in the `<custom_option>=<value>[,..]` format, where `<custom_option>` is an option name and `<value>` is an option value	–	No
fdw_startup_cost	DOUBLE	The cost estimate for obtaining the first tuple from the data source. Positive double values are allowed. Can be used only in `SELECT` queries to ADQM ClickHouse	1000.0	No
fdw_tuple_cost	DOUBLE	The cost estimate for obtaining one tuple from the data source. Positive double values are allowed. Can be used only in `SELECT` queries to ADQM ClickHouse	0.01	No
fdw_tuples_count	DOUBLE	The estimate for the number of all rows in the data source. Does not take into account the query selectivity, `LIMIT` clauses, etc. Positive double values > `1` are allowed. Can be used only in `SELECT` queries to ADQM ClickHouse	100000.0	No

Validation rules for the hosts option

- The list of ClickHouse hosts should be specified in the following format: `<hostname>:<port> [, ...]`, where `<hostname>` is a name of each host and `<port>` is an HTTP port number to connect to the corresponding host.
- The maximum length of the `<hostname>` value is 255 characters.
- You can use in the `<hostname>` value digits `0-9`, ASCII characters `a-zA-Z`, hyphens `-`, underscores `_`, and dots `.`.
- The presence of the `<port>` substring for each `<hostname>` is required. Only digits `0-9` are allowed in the `<port>` value. The maximum length of the `<port>` value is 5 characters.
- The maximum length of the `hosts` value (255 (the `<hostname>` limit) × 1 (`:`) + 5 (the `<port>` limit) × 1 (`,`)) × 127 (number of hosts) = 33274 characters.

User mapping

To create a user mapping, use the `CREATE USER MAPPING` command. The basic command syntax is listed below:

```
CREATE USER MAPPING FOR { <username> | USER | CURRENT_USER | PUBLIC }
  SERVER <server_name>
  [ OPTIONS ( <option> '<value>' [, ... ] ) ]
```

where:

- `<username>` – a user name in ADB. The following constants are allowed:
  - `USER` – the current user who established the ADB connection.
  - `PUBLIC` – all present and future ADB users.
- `<server_name>` – a server name.
- `<option>` – user mapping options, which typically include a user name and a password to connect to an external data source. The options that are available for ADB ClickHouse Connector are listed in the User mapping options table.
- `<value>` – option values.

NOTE

- To create a user mapping, you should be the owner of the corresponding server.
- The full description of the `CREATE USER MAPPING` command syntax is available in the Greenplum documentation.
- To edit a user mapping definition, use the ALTER USER MAPPING command. To delete a user mapping, use DROP USER MAPPING.

User mapping options

Name	Type	Description	Default	Required
clickhouse_username	TEXT	A user name in ClickHouse	–	Yes
clickhouse_password	TEXT	A user password in ClickHouse. If there is no password (for example, in the test environment), an empty string is specified	–	Yes

Foreign table

To create a foreign table, use the `CREATE FOREIGN TABLE` command. The basic command syntax is listed below:

```
CREATE FOREIGN TABLE [ IF NOT EXISTS ] <table_name> ( [
    <column_name> <data_type> [ COLLATE <collation> ] [ <column_constraint> [ ... ] ]
    [, ... ]
] )
  SERVER <server_name>
  [ OPTIONS ( <option> '<value>' [, ... ] ) ]
```

where:

- `<table_name>` – a foreign table name in ADB.
- `<column_name>` – a column name.
- `<data_type>` – a column data type.
- `<collation>` – a column collation.
- `<column_constraint>` – a constraint defined at the column level. The name `<constraint_name>` is given optionally. The syntax:

```
[ CONSTRAINT <constraint_name> ]
{ NOT NULL |
  NULL |
  DEFAULT <default_expr> }
```

Possible constraints:

- `NOT NULL` – specifies that the column is not allowed to contain null values.
- `NULL` – specifies that the column is allowed to contain null values. It is the default behavior (unless `NOT NULL` is specified).
- `DEFAULT` – sets the default column value equal to `<default_expr>`.

- `<server_name>` – a server name.
- `<option>` – foreign table options. For ADB ClickHouse Connector, all options defined at the server level can be overwritten at the foreign table level (partially or fully). When you specify an option for a server and a foreign table at the same time, the table level takes precedence. Additionally, at the foreign table level, two more options are available (see Foreign table options below).
- `<value>` – option values.

NOTE

- To create a foreign table, you need the `USAGE` privilege on the corresponding server and on all column data types that are used in the table definition. The user who creates the foreign table becomes its owner.
- The full description of the `CREATE FOREIGN TABLE` command syntax is available in the Greenplum documentation.
- To edit a foreign table definition, use the ALTER FOREIGN TABLE command. To drop a foreign table, use DROP FOREIGN TABLE.

Foreign table options

Name	Type	Description	Default	Required
resource	TEXT	A table name in ClickHouse. If you need your own strategy for distribution data across hosts (sharding), you should insert data into the distributed ClickHouse table with the sharding key configured. To do this, specify the distributed table name in the `resource` option. When writing data to a distributed table, remember that physical (local) tables should be present on all hosts in the ClickHouse cluster, otherwise the connector will return an error. The special value should match the following regular expression: `^[a-zA-Z_][0-9a-zA-Z_]*$`	–	Yes
cluster	TEXT	A cluster name in ClickHouse. For more information, see Typical cluster in the ADQM documentation. If you specify the `cluster` option, the list of ClickHouse hosts should be defined in the `hosts` option at the foreign table level and consist of one element (`<hostname>:<port>`), even if it has been already declared at the server level. Otherwise, there may be an ambiguous situation when there is a list of hosts at the server level, but the work is actually done with hosts received from the ClickHouse cluster metadata. The `cluster` option provides the convenience of users. With that option, it is enough to specify a cluster name and one entry point, the full list of hosts will be received from ClickHouse. The load distribution strategy will be still distributed according to the selected `distribution_type` value (see above). The maximum `cluster` length is 128 characters	–	No

ADB ClickHouse Connector usage examples

Insert data

Select data

- Correct example
- Error example

This article describes how to transfer data between ADB and a distributed table in ADQM 25.3.2.39 via ADB ClickHouse Connector. The following prerequisites are met:

- The ADQM cluster is installed according to the Online installation guide on the following hosts: `dev-adqm-01.ru-central1.internal`, `dev-adqm-02.ru-central1.internal`, `dev-adqm-03.ru-central1.internal`, `dev-adqm-04.ru-central1.internal`
- The `default` database exists in ADQM.
- The `default` user exists in ADQM.
- The `default_cluster` cluster is defined in the `remote_servers` section of the *config.xml* file in ADQM. For more information, see Typical cluster in the ADQM documentation.
- All ADB nodes have access to the `8123` HTTP port on all ADQM nodes through which you plan to load data.

Insert data

To check that you can add data to ADQM from ADB, follow the steps:

1. Connect to the `default` database of the ADQM cluster under the `default` user (for example, via clickhouse-client). Create the following tables in the given order.

   - The `test_local` local table:

```
CREATE TABLE test_local ON CLUSTER default_cluster
(
    id Int32,
    value_string String
)
ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}/test_local', '{replica}')
ORDER BY id;
```

   - The `test_distr` distributed table:

```
CREATE TABLE test_distr ON CLUSTER default_cluster AS default.test_local
ENGINE = Distributed(default_cluster, default, test_local, rand());
```

2. Connect to the `adb` database of the ADB cluster under the `gpadmin` user (for example, via `psql`). Create the following objects in the given order.

   - The `clickhouse_server` server:

```
CREATE SERVER clickhouse_server
FOREIGN DATA WRAPPER tsh_fdw
OPTIONS (
        database 'default',
        hosts 'dev-adqm-01.ru-central1.internal:8123, dev-adqm-02.ru-central1.internal:8123, dev-adqm-03.ru-central1.internal:8123, dev-adqm-04.ru-central1.internal:8123',
        distribution_type 'random',
        lines_batch_size '100000',
        send_compressed 'true',
        send_delay '300',
        insert_distributed_sync 'true',
        use_staging 'true',
        staging_table_name_format '${_tmp_$}');
```

   - The user mapping for the `gpadmin` user:

```
CREATE USER MAPPING FOR gpadmin
SERVER clickhouse_server
OPTIONS (clickhouse_username 'default', clickhouse_password '');
```

   - The `tshemali_test` foreign table:

```
CREATE FOREIGN TABLE tshemali_test (id INT, value_string TEXT)
SERVER clickhouse_server
OPTIONS (resource 'test_distr',
         hosts 'dev-adqm-01.ru-central1.internal:8123',
         cluster 'default_cluster');
```

> **IMPORTANT**
>
> Since the `cluster` option is defined, the work will be essentially produced with the hosts obtained from the ADQM cluster metadata. Due to this, remember to overwrite the `hosts` option value defined for `clickhouse_server` at the server level and leave only one host in the option value at the table level.

3. In ADB, insert some data into the `tshemali_test` foreign table:

```
INSERT INTO tshemali_test VALUES
(1, 'test1'),
(2, 'test2'),
(3, 'test3'),
(4, 'test4'),
(5, 'test5'),
(6, 'test6'),
(7, 'test7'),
(8,'test8'),
(9,'test9'),
(10,'test10');
```

   Result:

```
INSERT 0 10
```

4. In ADQM, check that data from ADB has been successfully transferred:

```
SELECT * FROM test_distr;
```

   Result:

```
┌─id─┬─value_string─┐
│  5 │ test5        │
│  7 │ test7        │
│  9 │ test9        │
│ 10 │ test10       │
│  3 │ test3        │
│  6 │ test6        │
│  8 │ test8        │
│  1 │ test1        │
│  4 │ test4        │
│  2 │ test2        │
└────┴──────────────┘

10 rows in set. Elapsed: 0.008 sec.
```

Select data

> **NOTE**
>
> ADB ClickHouse Connector supports the ability to select data from ADQM/ClickHouse to ADB starting with the 7.0.8.3 version in ADB 6 and the 7.4.0 version in ADB 7. However, to use a foreign table in ADB for reading, you should specify column names that match exactly the corresponding names in a source table in ADQM/ClickHouse.

Correct example

To check that ADQM data can be read from ADB, do the following:

1. Perform steps 1–2 that are listed above (if you have not passed them yet).
2. Delete data from the `test_local` table in ADQM:

```
ALTER TABLE default.test_local ON CLUSTER default_cluster DELETE WHERE true;
```

3. In ADQM, add some data to the `test_distr` table:

```
INSERT INTO test_distr VALUES
(1, 'test1'),
(2, 'test2'),
(3, 'test3'),
(4, 'test4'),
(5, 'test5'),
(6, 'test6'),
(7, 'test7'),
(8,'test8'),
(9,'test9'),
(10,'test10');
```

   Result:

```
Query id: 9eec272c-e292-46c5-be17-33bee1b0188e

Ok.

10 rows in set. Elapsed: 0.010 sec.
```

4. Check that data added to ADQM can be successfully selected in ADB:

```
SELECT * FROM tshemali_test ORDER BY id;
```

   Result:

```
 id | value_string
----+--------------
  1 | test1
  2 | test2
  3 | test3
  4 | test4
  5 | test5
  6 | test6
  7 | test7
  8 | test8
  9 | test9
 10 | test10
(10 rows)
```

Error example

The following example shows that reading data from ADQM/ClickHouse to ADB is impossible if column names in the foreign ADB table and the source ADQM/ClickHouse table do not match:

1. Perform all steps from the previous example with correct data reading (if you have not passed them yet).
2. Ensure that reading data based on the current foreign table structure is successful in ADB:

```
SELECT * FROM tshemali_test ORDER BY id;
```

   Result:

```
 id | value_string
----+--------------
  1 | test1
  2 | test2
  3 | test3
  4 | test4
  5 | test5
  6 | test6
  7 | test7
  8 | test8
  9 | test9
 10 | test10
(10 rows)
```

3. Rename some columns of the `tshemali_test` table in ADB:

```
ALTER FOREIGN TABLE tshemali_test RENAME value_string TO wrong_string;
```

4. Check again the ability to select data from `tshemali_test` in ADB:

```
SELECT * FROM tshemali_test ORDER BY id;
```

   The following error is displayed:

```
ERROR:  CH easy datum. HTTP error: 404; CH message: Code: 47. DB::Exception: Unknown expression identifier `wrong_string` in scope SELECT id, wrong_string FROM default.test_local. (UNKNOWN_IDENTIFIER) (version 25.3.2.39) (ch_easy_datum.c:141)  (seg1 slice1 10.92.38.12:10000 pid=1648660) (ch_easy_datum.c:141)
```

> **NOTE**
>
> If names are the same only for part of columns in the foreign table in ADB and the source table in ADQM/ClickHouse — the SQL query succeeds while the resulting dataset uses only the specified columns.

Integration between ADB and Kafka

Daria Barysheva

To Table of Contents

To integrate ADB and Kafka, you can use one of the following connectors:

- **ADB to Kafka Connector** — based on PXF and external tables. Implements data load from ADB to Kafka. For more information, see:
  - ADB to Kafka Connector installation
  - ADB to Kafka Connector configuration
  - ADB to Kafka Connector usage examples
- **Kafka to ADB Connector** — based on a foreign data wrapper mechanism. Uses librdkafka for communication with Kafka and implements transactional data load from Kafka to ADB. For more information, see:
  - Kafka to ADB Connector installation
  - Kafka to ADB Connector configuration
  - Kafka to ADB Connector usage examples

ADB to Kafka Connector installation

Daria Barysheva

To Table of Contents

To install ADB to Kafka Connector, follow the steps:

1. Make sure that PXF and ADB to Kafka services are installed. For information on how to add services to ADB clusters, see Add services.
2. Add the new custom profile `kafka` to the PXF configuration file */var/lib/pxf/conf/pxf-profiles.xml* on **coordinator**. To edit the file, you can use the `vi` or `vim` command:

```
$ sudo vi /var/lib/pxf/conf/pxf-profiles.xml
```

The content of the changed file can look as follows. In the given example, the file does not contain other profiles:

```
<profiles>
    <profile>
        <name>kafka</name>
        <description>A profile for export data into Apache Kafka</description>
        <plugins>
            <accessor>org.greenplum.pxf.plugins.kafka.KafkaAccessor</accessor>
            <resolver>org.greenplum.pxf.plugins.kafka.KafkaResolver</resolver>
        </plugins>
        <optionMappings>
            <!-- Kafka properties -->
            <mapping option="BOOTSTRAP_SERVERS" property="kafka.bootstrap.servers"/>
            <mapping option="SECURITY_PROTOCOL" property="kafka.property.security.protocol" />
            <mapping option="SASL_MECHANISM" property="kafka.property.sasl.mechanism" />
            <mapping option="TRUSTSTORE_LOCATION" property="kafka.property.ssl.truststore.location" />
            <mapping option="TRUSTSTORE_PASSWORD" property="kafka.property.ssl.truststore.password" />
            <mapping option="KEYSTORE_LOCATION" property="kafka.property.ssl.keystore.location" />
            <mapping option="KEYSTORE_PASSWORD" property="kafka.property.ssl.keystore.password" />
            <mapping option="KERBEROS_SERVICE_NAME" property="kafka.property.sasl.kerberos.service.name" />

            <!-- Kafka JAAS properties -->
            <mapping option="KERBEROS_PRINCIPAL" property="kafka.jaas.property.sasl.kerberos.principal" />
            <mapping option="KERBEROS_KEYTAB" property="kafka.jaas.property.sasl.kerberos.keytab" />
            <mapping option="KERBEROS_USE_KEYTAB" property="kafka.jaas.property.sasl.kerberos.useKeyTab" />
            <mapping option="KERBEROS_STORE_KEY" property="kafka.jaas.property.sasl.kerberos.storeKey" />
            <mapping option="KERBEROS_USE_TICKET_CACHE" property="kafka.jaas.property.sasl.kerberos.useTicketCache" />
            <mapping option="KERBEROS_DEBUG" property="kafka.jaas.property.sasl.kerberos.debug" />
            <mapping option="SASL_USER" property="kafka.jaas.property.sasl.user" />
            <mapping option="SASL_USER_PASSWORD" property="kafka.jaas.property.sasl.user.password" />
            <mapping option="JAAS_CONFIG_FILE" property="kafka.jaas.property.config.file" />

            <!-- General properties -->
            <mapping option="BATCH_SIZE" property="kafka.batch.size"/>
            <mapping option="KAFKA_ADMIN_CONNECTION_TIMEOUT" property="kafka.admin.close.connection.timeout"/>
            <mapping option="TOPIC_AUTO_CREATE_FLAG" property="kafka.topic.auto.create"/>
            <mapping option="AVRO_DEFAULT_DECIMAL_PRECISION" property="avro.decimal.default.precision" />
            <mapping option="AVRO_DEFAULT_DECIMAL_SCALE" property="avro.decimal.default.scale" />
        </optionMappings>
    </profile>
</profiles>
```

NOTE

The directory, where PXF configuration files are located, is defined by the `PXF_BASE` environment variable. The default value is */var/lib/pxf*. The path may differ in your environment.

3. Log in under the default user `gpadmin`. All the commands listed in the subsequent steps should be performed on **coordinator**:

```
$ sudo su - gpadmin
```

4. Synchronize the PXF configuration on all hosts in the ADB cluster:

```
$ pxf cluster sync
```

Result:

```
Syncing PXF configuration files from coordinator host to standby coordinator host and 2 segment hosts...
PXF configs synced successfully on 3 out of 3 hosts
```

5. Restart PXF:

```
$ pxf cluster restart
```

Result:

```
Restarting PXF on coordinator host, standby coordinator host, and 2 segment hosts...
PXF restarted successfully on 4 out of 4 hosts
```

ADB to Kafka Connector configuration

By Anton Borisov

Contents

Table of contents

Create a scalable external table

Use the SERVER option

Use a secure connection

Custom configuration of the SASL authentication mechanisms

Greenplum and AVRO data types

To save time on ADB to Kafka via ADB to Kafka Connector, you should first create a scalable external table on the ADB cluster side. In the `LOCATION` clause, we list PXF protocol and the Kafka topic from which we want to read data.

Also in the `LOCATION` clause, we list the `CREATE WRITABLE EXTERNAL TABLE` command. The basic command syntax is below:

```
CREATE WRITABLE EXTERNAL TABLE <table_name> (
    [ <column_name> <data_type> [, ...] | LIKE <other_table> ])
LOCATION ('pxf://<kafka_topic>?PROFILE=kafka&BOOTSTRAP_SERVERS=<kafka_server_host_name>')
FORMAT 'CUSTOM' (FORMATTER='pxfwritable_export');
INSERT INTO <table_name> SELECT ... FROM <source_table>;
```

where

- `<table_name>` — an external table name in ADB;
- `<column_name>` — a column name;
- `<data_type>` — a column data type;
- `<other_table>` — a table name, which column names, column data types, and distribution policy will be copied to the new external table. In this case, the column definitions in it should coincide with the specified in the create table command;
- `<kafka_topic>` — a Kafka topic name;
- `<kafka_server_host_name>` — a Kafka server host name and port, for example, `localhost:9092`. For more information, see the Kafka documentation;
- `<source_table>` — a name of the table in ADB, the data from which will be written to Kafka. Column names are taken the following options: `format options`, `kafka options`, `producer options`, `session level options`, and `profile level options`, which options list for Kafka, in the table below.

`INSERT` — an insert command.

> **NOTE**
>
> - For the optimal performance, the `PROFILE=kafka` in the external table should be similar to the parity in the source table from which data is transferred. For example, if the source table has 8 segments, then for each data block, the PXF segments select the individual Kafka partitions. For this purpose, it is necessary to create a Kafka topic with 8 partitions. Otherwise, some PXF segments will receive more than one block of data, while others will remain idle.
> - To view the full syntax of the `CREATE EXTERNAL TABLE` command, see the official Greenplum documentation.
> - To alter an external table definition, use the `ALTER EXTERNAL TABLE` command. To delete an external table, use `DROP EXTERNAL TABLE`.

General options

Name	Description	Default	Required
KAFKA_SESSION_TIMEOUT_MS	A grace period during which current operations are completed before the server stops waiting for acknowledgments from a consumer. If no heartbeats reach the server in a session timeout, the consumer is removed from the consumer group and a rebalance begins. Value in milliseconds.	30000	No
BATCH_SIZE	A number of rows that producers should batch in one Kafka message.	4096	No
TOPIC_AUTO_CREATE_FLAG	A flag that indicates whether a Kafka topic should be created automatically if it does not exist when data is written to it. The topic will be created with one partition and replication factor 1.	true	No
AVRO_DEFAULT_DECIMAL_PRECISION	A maximum number of digits in a number (related to `DECIMAL` data type).	38	No
AVRO_DEFAULT_DECIMAL_SCALE	A maximum number of digits to the right of the decimal point (related to `DECIMAL` data type).	18	No

Kafka options

Name	Description	Default	Required
BOOTSTRAP_SERVERS	A comma-separated list of host and port pairs, which is specified in the following format: `<hostname1>:<port1>,<hostname2>:<port2>`.		true
SECURITY_PROTOCOL	A security protocol that is used to communicate with Kafka brokers. Valid values are: - PLAINTEXT - SASL_PLAINTEXT - SASL_SSL - SSL (one-way and two-way authentication)	PLAINTEXT	No
SASL_MECHANISM	A SASL mechanism that is used for client connections. Possible values: - PLAIN - SCRAM-SHA-256 - SCRAM-SHA-512 If you want another authentication mechanism, you can add it to the list of supported ones in the configuration file.	PLAIN	No
TRUSTSTORE_LOCATION	A path to the truststore file.		No
TRUSTSTORE_PASSWORD	A password for the truststore file.		No
KEYSTORE_LOCATION	A path to the keystore file.		No
KEYSTORE_PASSWORD	A password for the keystore file.		No
KERBEROS_SERVICE_NAME	A name of the Kerberos principal used by Kafka. Can be used with Kerberos authentication.		No

JAAS options for the SASL SCRAM mechanism (kafkasc)

These options are used when `SECURITY_PROTOCOL` is set to `SASL_PLAINTEXT` or `SASL_SSL` and `SASL_MECHANISM` is set to `SCRAM-SHA-256` or `SCRAM-SHA-512`. Since each parameter can depend on others, all of them are mandatory.

> **NOTE**
>
> For more information on JAAS configuration, see JAAS Configuration in the Kafka documentation.

Name	Description	Default	Required
KERBEROS_PRINCIPAL	A name of the Kerberos principal that should be used. The principal can be a simple username or a GSS-API Kerberos principal, when Kerberos authentication is used with `sasl.jaas.config` property.		No
KERBEROS_KEYTAB	A file name of the keytab to get a principal secret key.		No
KERBEROS_USE_KEYTAB	A flag that indicates whether to get a principal secret key from a keytab.		No
KERBEROS_STORE_KEY	A flag that indicates whether to store keys2ed or a principal in the keytab of the local private credentials.		No
KERBEROS_USE_TICKET_CACHE	A flag that indicates whether to obtain a ticket granting ticket (TGT) from the ticket cache.		No
KERBEROS_RENEW	A flag that indicates whether to output debug messages.		No
JAAS_CONFIG_FILE	A path to the JAAS configuration file. Use it instead of the `sasl.jaas.config` property. If you set it, you don't need to set the next configuration. See details in docs.		No

JAAS options for the SASL PLAIN, SCRAM-256, or SCRAM-512 mechanism

These options are used when `SECURITY_PROTOCOL` is set to `SASL_PLAINTEXT` or `SASL_SSL` and `SASL_MECHANISM` is set to `PLAIN`, `SCRAM-SHA-256`, or `SCRAM-SHA-512`.

Name	Description	Default	Required
SASL_USER	A user name for client connections.		Set if `SASL_MECHANISM` is `PLAIN`, `SCRAM-SHA-256`, or `SCRAM-SHA-512`
JAAS_CONFIG_FILE	A password of the `SASL_USER` user.		Set if `SASL_MECHANISM` is `PLAIN`, `SCRAM-SHA-256`, or `SCRAM-SHA-512`

JAAS_CONFIG_FILE

ADB to Kafka connector uses Java JAAS configuration to connect to Kafka. When connecting to Kafka via `SASL_PLAINTEXT` and `SASL_SSL` protocols. For JAAS configuration, the `JAAS_CONFIG` parameter is used. Alternatively, you can use the `JAAS_CONFIG_FILE` parameter and add options for the Kafka JAAS mechanism (except `SASL_USER` and `SASL_PASSWORD`) to the file.

- Set options in the file as shown in the example. JAAS options for the SASL SCRAM mechanism (kafkasc) and options for the Kafka JAAS mechanism (except `SASL_USER` and `SASL_PASSWORD`).
- Specify the path to the file in the `JAAS_CONFIG_FILE` parameter. The `JAAS_CONFIG_FILE` parameter is used only when specified for the recommended table as an example of properties are read from the file.
- Specify the path to the file in the `SASL_CONFIG_FILE` parameter. If the `SASL_CONFIG_FILE` parameter exists, we expect for a specific JAAS configuration. The file, which path is set in the `SASL_CONFIG_FILE` value, should contain only one line. The example is below.

File example for SASL_MECHANISM = PLAIN:

```
org.apache.kafka.common.security.plain.PlainLoginModule required username="kafka_user" password="kafka_password";
```

File example for SASL_MECHANISM = SCRAM-SHA-256/SCRAM-SHA-512:

```
com.sun.security.auth.module.Krb5LoginModule required principal="kafka_user@EXPRIMP.INTERNAL"
useKeyTab=true storeKey=true keyTab="/etc/security/keytabs/kafka.keytab" client=true;or "org.apache.kafka.common.security.scram.ScramLoginModule required username="kafka_user" password="kafka_password";
```

File example for SASL_MECHANISM = SCRAM-SHA-256/SCRAM-SHA-512:

```
com.sun.security.auth.module.Krb5LoginModule required principal="kafka_user@EXPRIMP.INTERNAL"
useKeyTab=true storeKey=true keyTab="/etc/security/keytabs/kafka.keytab" client=true;or "org.apache.kafka.common.security.scram.ScramLoginModule required username="kafka_user" password="kafka_password";
```

Before starting queries in an external table, you should copy the file to each ADB segment host.

Use the SERVER option

By using `SERVER=<server_name>` in the external table creation query, you can specify from the configuration file without explicitly specifying them in the `LOCATION` clause.

1. Add a new directory in `$PXF_BASE/servers` as `<servername>`. The new directory name will be used as a server name `<server_name>`.

```
$ sudo mkdir /var/lib/pxf/servers/server_name
```

> **NOTE**
>
> The existing default PXF configuration files are located in directory the `PXF_BASE` environment variable. The default value is `/var/lib/pxf`. The path may differ in your environment.

2. Create the Kafka site.xml configuration file in the `/var/lib/pxf/servers/server_name` directory.

```
$ sudo vi /var/lib/pxf/servers/server_name/kafka-site.xml
```

The example of Kafka site.xml is listed below.

kafka-site.xml example

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration>
    <property>
        <name>kafka.bootstrap.servers</name>
        <value>host1.vmw.e.ru-central1.internal:9092,host2.vmw.e.ru-central1.internal:9092,host3.vmw.e.ru-central1.internal:9092</value>
    </property>
    <property>
        <name>kafka.sasl.jaas.config</name>
        <value>com.sun.security.auth.module.Krb5LoginModule required
        principal="kafka_user@EXPRIMP.INTERNAL"
        useKeyTab=true
        storeKey=true
        keyTab="/etc/security/keytabs/kafka.keytab"
        client=true;</value>
    </property>
    <property>
        <name>kafka.security.protocol</name>
        <value>SASL_PLAINTEXT</value>
    </property>
    <property>
        <name>kafka.sasl.mechanism</name>
        <value>GSSAPI</value>
    </property>
    <property>
        <name>kafka.sasl.kerberos.service.name</name>
        <value>kafka</value>
    </property>
    <property>
        <name>kafka.session.timeout.ms</name>
        <value>30000</value>
    </property>
    <property>
        <name>kafka.batch.size</name>
        <value>4096</value>
    </property>
    <property>
        <name>kafka.topic.auto.create</name>
        <value>true</value>
    </property>
    <property>
        <name>kafka.avro.default.decimal.precision</name>
        <value>38</value>
    </property>
    <property>
        <name>kafka.avro.default.decimal.scale</name>
        <value>18</value>
    </property>
</configuration>
```

3. Synchronize the PXF configuration on all hosts in the ADB cluster.

```
$ pxf cluster sync

  Result

Syncing PXF configuration files from coordinator host to 3 standby coordinator host and 2 segment hosts...
PXF configs synced successfully on 5 out of 5 hosts
```

4. Restart PXF.

```
$ pxf cluster restart

  Result

Restarting PXF on coordinator host, standby coordinator host, and 2 segment hosts...
PXF restarted successfully on 5 out of 5 hosts
```

5. When creating an external table, specify `SERVER=<server_name>` in the `LOCATION` clause. Go to the full syntax options.

```
CREATE WRITABLE EXTERNAL TABLE <table_name> (
    [ <column_name> <data_type> [, ...] | LIKE <other_table> ])
LOCATION (
    'pxf://<kafka_topic>?PROFILE=kafka&SERVER=<server_name>'
FORMAT 'CUSTOM' (FORMATTER='pxfwritable_export');
```

Use custom options

In addition to ADB to Kafka Connector options mentioned above, you can define any other property available for a Kafka producer. There are two ways to set custom options:

- Kafka-style properties in the `LOCATION` clause, for example, `kafka.acks=all`. For example:

```
CREATE WRITABLE EXTERNAL TABLE test_w (id, t TEXT)
LOCATION ('pxf://test_topic?PROFILE=kafka&BOOTSTRAP_SERVERS=vmw.e.ru-central1.internal:9092,vmw.e.ru-central1.internal:9092,vmw.e.ru-central1.internal:9092&kafka.acks=all')
FORMAT 'CUSTOM' (FORMATTER='pxfwritable_export');
INSERT INTO test_w SELECT * FROM test_r;
```

- Add Kafka properties to the kafka-site.xml file for a server that will be specified in the `SERVER` option. For example:

```
<property>
    <name>kafka.property.delivery.timeout.ms</name>
    <value>120000</value>
</property>
```

> **NOTE**
>
> If you define custom options, you should add the `kafka.property.` prefix to property names (see kafka.delivery.timeout.ms above). Due to this, the parameter `timeout.ms` will be ignored, and the default `kafka.property.timeout.ms` will be used.

Custom configuration of the SASL authentication mechanism

If you fully want to configure a specific SASL authentication mechanism, then you can use the `JAAS_CONFIG` file (see `SASL_MECHANISM`), you are to fully configure the JAAS configuration file. For example, for the `GSSAPI` mechanism, you should have to use only `SECURITY_PROTOCOL` parameters and the JAAS configuration file.

1. `SECURITY_PROTOCOL` — `SASL_SSL` or `SASL_PLAINTEXT` depending on the Kafka broker configuration.
2. `SASL_MECHANISM` — `GSSAPI`.
3. Set required Kafka properties in the JAAS configuration file. See the Kerberos client options for information.
4. Set the `JAAS_CONFIG_FILE` to the path where it is on disk/nfs and if the file is the same on each segment host. For example, you are to copy it to the folder with the Kafka server.
5. Create a table using the following query:

```
CREATE WRITABLE EXTERNAL TABLE kafka_kk_w(username TEXT, t TEXT)
LOCATION ('pxf://test_topic?PROFILE=kafka&BOOTSTRAP_SERVERS=host1.vmw.e.ru-central1.internal:9092,host2.vmw.e.ru-central1.internal:9092,host3.vmw.e.ru-central1.internal:9092&SECURITY_PROTOCOL=SASL_PLAINTEXT&SASL_MECHANISM=GSSAPI&JAAS_CONFIG_FILE=/etc/security/jaas/kafka_client.conf')
FORMAT 'CUSTOM' (FORMATTER='pxfwritable_export');
```

In case of having the file in the /etc/krb5.conf/krb5.keytab server directory, the kdb definitions would look like this:

```
CREATE WRITABLE EXTERNAL TABLE kafka_kk_w(username TEXT, t TEXT)
LOCATION ('pxf://test_topic?PROFILE=kafka&BOOTSTRAP_SERVERS=host1.vmw.e.ru-central1.internal:9092,host2.vmw.e.ru-central1.internal:9092,host3.vmw.e.ru-central1.internal:9092&SECURITY_PROTOCOL=SASL_PLAINTEXT&SASL_MECHANISM=GSSAPI&JAAS_CONFIG_FILE=/etc/krb5.conf/krb5.keytab')
FORMAT 'CUSTOM' (FORMATTER='pxfwritable_export');
```

Greenplum and AVRO data types

The following table describes how Greenplum data types are converted into AVRO types when the ADB to Kafka Connector is used:

Greenplum type	AVRO primitive type	AVRO logical type
BOOLEAN	BOOLEAN	-
TEXT	STRING	-
VARCHAR	STRING	-
TIMESTAMP	LONG	timestamp-micros
BIGINT	LONG	-
TIME	LONG	time-micros
NUMERIC	DOUBLE	-
FLOATS	DOUBLE	-
REAL	FLOAT	-
SMALLINT	INT	-
INTEGER	INT	-
DATE	INT	date

To Table of Contents ↑

This article describes how to transfer data from ADB to Kafka using the [ADD to Kafka Connector](). The following prerequisites are met:

- [Kafka Connector](#) is installed on your Kafka server. Instructions: [apply Kafka Connector configuration](), [apply Kafka Connector configuration (with SERVER option)](), [apply Kafka Connector configuration (with SASL mechanism)](), [apply Kafka Connector configuration (with SERVER option and SASL mechanism)]().
- A Kafka 2.4.1 or later cluster is deployed. Instructions: [install Kafka]().
- The [JDK]() 8 version is installed.
- The [ADB]() cluster and ADD 3.0 are installed. Instructions: [install ADB and ADD]().

NOTE

In this article, we assume that the [Kafka]() cluster is already deployed, you have created a topic named `test` and ensured that it is available for writing and reading.

TIP

- Tutorials on Kafka installation: [Kafka quickstart]() and [Kafka tutorial]().
- Tool used in tutorials: if you specify a non-existent topic in the [Kafka console producer](), [Kafka will create]() a topic with default parameters.

PLAINTEXT security protocol (by default)

Without SERVER option

1. Define a topic to which the data will be transferred, e.g. `test`. [Kafka]() will create the topic automatically.

2. Switch to the Kafka user. For example, `sudo -i kafka_user`. Instructions: [install ADB and ADD]().

3. Connect to the [ADB]() database as the ADB administrator (user `ADMIN`) and run the commands:

```
$ sudo -i kafka_user

$ adcli adb
```

4. Create a test database with the following commands:

```
CREATE WRITABLE EXTERNAL TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
LOCATION ('kafka://kafka_server_ip_address:9092/test?
format=CSV&key_mode=none&value_mode=none')
FORMAT 'CUSTOM' FORMATTER 'gpfwritable.export';

CREATE TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
DISTRIBUTED BY (id);

INSERT INTO test_adb_to_kafka VALUES
    (1, 'Test1', 'Test1'),
    (2, 'Test2', 'Test2'),
    (3, 'Test3', 'Test3');
```

5. Verify that the test data is written to the topic. To do this, on the new terminal window, in the root directory, run the following command:

```
$ /usr/local/kafka/bin/kafka-console-consumer.sh --bootstrap-server kafka_server_ip_address:9092 --topic test --from-beginning
{"id":1,"name":"Test1","value":"Test1"}
{"id":2,"name":"Test2","value":"Test2"}
{"id":3,"name":"Test3","value":"Test3"}
^CProcessed a total of 3 messages
```

The command output is shown between `{` and `}`.

With SERVER option

1. Define a server for the [Kafka]() cluster in the [ADD]() configuration. Instructions: [configure ADD]().

2. In ADB, create a server with the [`CREATE SERVER`]() command and define the Kafka brokers in the `OPTIONS` parameter:

```
CREATE SERVER kafka_server FOREIGN DATA WRAPPER kafka_fdw
    OPTIONS (brokers 'kafka_server_ip_address:9092');

GRANT USAGE ON FOREIGN SERVER kafka_server TO adb_user;
```

3. Create a test database with the [`SERVER`]() option and specify the Kafka topic in the `OPTIONS` parameter:

```
CREATE WRITABLE EXTERNAL TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
LOCATION ('kafka://test?format=CSV&key_mode=none&value_mode=none')
FORMAT 'CUSTOM' FORMATTER 'gpfwritable.export'
SERVER kafka_server;

CREATE TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
DISTRIBUTED BY (id);

INSERT INTO test_adb_to_kafka VALUES
    (1, 'Test1', 'Test1'),
    (2, 'Test2', 'Test2'),
    (3, 'Test3', 'Test3');
```

4. Verify that the test data is written to the topic. To do this, on the new terminal window, in the root directory, run the following command:

```
$ /usr/local/kafka/bin/kafka-console-consumer.sh --bootstrap-server kafka_server_ip_address:9092 --topic test --from-beginning
{"id":1,"name":"Test1","value":"Test1"}
{"id":2,"name":"Test2","value":"Test2"}
{"id":3,"name":"Test3","value":"Test3"}
^CProcessed a total of 3 messages
```

The command output is shown between `{` and `}`.

SASL_PLAINTEXT security protocol

PLAIN mechanism

1. Configure the [Kafka]() cluster to support [Simple SASL PLAINTEXT authentication]() and the [PLAIN]() SASL mechanism.

2. Create a topic to which the data will be transferred. For example, `test`. Instructions: [create a topic]().

3. Switch to the Kafka user. For example, `sudo -i kafka_user`. Instructions: [install ADB and ADD]().

4. Add the [JAAS]() configuration to the [ADD]() configuration. Instructions: [configure ADD]().

5. Add the [SASL authentication parameters]() to the [ADD]() configuration. Instructions: [configure ADD]().

Specify the following parameters in the `/etc/add/pxf-application.properties` file:

```
kafka.sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule required username="user_name" password="user_password";
kafka.sasl.mechanism=PLAIN
```

6. Restart the [ADD]() service:

```
$ add restart
```

7. Connect to the [ADB]() database as the ADB administrator (user `ADMIN`) and run the commands:

```
$ sudo -i gpadmin

$ adcli adb
```

8. Create a test database with the following commands:

```
CREATE WRITABLE EXTERNAL TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
LOCATION ('kafka://kafka_server_ip_address:9092/test?format=CSV&key_mode=none&value_mode=none&kafka_property=security.protocol%3dSASL_PLAINTEXT%26sasl.mechanism%3dPLAIN')
FORMAT 'CUSTOM' FORMATTER 'gpfwritable.export';

CREATE TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
DISTRIBUTED BY (id);

INSERT INTO test_adb_to_kafka VALUES
    (1, 'Test1', 'Test1'),
    (2, 'Test2', 'Test2'),
    (3, 'Test3', 'Test3');
```

9. Verify that the test data is written to the topic. To do this, on the new terminal window, in the root directory, run the following command:

```
$ /usr/local/kafka/bin/kafka-console-consumer.sh --bootstrap-server kafka_server_ip_address:9092 --topic test --from-beginning
{"id":1,"name":"Test1","value":"Test1"}
{"id":2,"name":"Test2","value":"Test2"}
{"id":3,"name":"Test3","value":"Test3"}
^CProcessed a total of 3 messages
```

The command output is shown between `{` and `}`.

GSSAPI mechanism (Kerberos)

1. Configure the [Kafka]() cluster to support [Simple SASL PLAINTEXT authentication]() and the [GSSAPI]() SASL mechanism.

2. Create a topic to which the data will be transferred. For example, `test`. Instructions: [create a topic]().

3. Switch to the Kafka user. For example, `sudo -i kafka_user`. Instructions: [install ADB and ADD]().

4. Add the [JAAS]() configuration to the [ADD]() configuration. Instructions: [configure ADD]().

5. Add the [SASL authentication parameters]() to the [ADD]() configuration. Instructions: [configure ADD]().

Specify the following parameters in the `/etc/add/pxf-application.properties` file:

```
kafka.sasl.jaas.config=com.sun.security.auth.module.Krb5LoginModule required useKeyTab=true storeKey=true keyTab="/etc/security/keytabs/kafka_client.keytab" principal="kafka_client_principal";
kafka.sasl.mechanism=GSSAPI
```

6. Restart the [ADD]() service:

```
$ add restart
```

7. Connect to the [ADB]() database as the ADB administrator (user `ADMIN`) and run the commands:

```
$ sudo -i gpadmin

$ adcli adb
```

8. Create a test database with the following commands:

```
CREATE WRITABLE EXTERNAL TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
LOCATION ('kafka://kafka_server_ip_address:9092/test?format=CSV&key_mode=none&value_mode=none&kafka_property=security.protocol%3dSASL_PLAINTEXT%26sasl.mechanism%3dGSSAPI%26sasl.kerberos.service.name%3dkafka')
FORMAT 'CUSTOM' FORMATTER 'gpfwritable.export';

CREATE TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
DISTRIBUTED BY (id);

INSERT INTO test_adb_to_kafka VALUES
    (1, 'Test1', 'Test1'),
    (2, 'Test2', 'Test2'),
    (3, 'Test3', 'Test3');
```

9. Verify that the test data is written to the topic. To do this, on the new terminal window, in the root directory, run the following command:

```
$ /usr/local/kafka/bin/kafka-console-consumer.sh --bootstrap-server kafka_server_ip_address:9092 --topic test --from-beginning
{"id":1,"name":"Test1","value":"Test1"}
{"id":2,"name":"Test2","value":"Test2"}
{"id":3,"name":"Test3","value":"Test3"}
^CProcessed a total of 3 messages
```

The command output is shown between `{` and `}`.

SASL_SSL security protocol with GSSAPI mechanism (Kerberos)

Before you start, make sure that you have configured the [Kafka]() cluster to support [Simple SASL SSL authentication]() and the [GSSAPI]() SASL mechanism.

1. Switch to the Kafka user. For example, `sudo -i kafka_user`. Instructions: [install ADB and ADD]().

2. Generate a client certificate. Instructions: [generate a client certificate]().

3. Generate a file keystore and convert keystore to pkcs12 format with the following commands:

```
$ keytool -importkeystore -srckeystore kafka.client.keystore.jks -destkeystore kafka.client.keystore.p12 -deststoretype PKCS12
```

4. Convert the keystore to pem format with the following command:

```
$ openssl pkcs12 -in kafka.client.keystore.p12 -out kafka.client.keystore.pem
```

5. Add the [JAAS]() configuration to the [ADD]() configuration. Instructions: [configure ADD]().

6. Add the [SASL authentication parameters]() to the [ADD]() configuration. Instructions: [configure ADD]().

Specify the following parameters in the `/etc/add/pxf-application.properties` file:

```
kafka.sasl.jaas.config=com.sun.security.auth.module.Krb5LoginModule required useKeyTab=true storeKey=true keyTab="/etc/security/keytabs/kafka_client.keytab" principal="kafka_client_principal";
kafka.sasl.mechanism=GSSAPI
kafka.security.protocol=SASL_SSL
kafka.ssl.truststore.location=/var/lib/add/conf/kafka.client.keystore.jks
kafka.ssl.truststore.password=password
```

7. Restart the [ADD]() service:

```
$ add restart
```

8. Connect to the [ADB]() database as the ADB administrator (user `ADMIN`) and run the commands:

```
$ sudo -i gpadmin

$ adcli adb
```

9. Create a test database with the following commands:

```
CREATE WRITABLE EXTERNAL TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
LOCATION ('kafka://kafka_server_ip_address:9092/test?format=CSV&key_mode=none&value_mode=none&kafka_property=security.protocol%3dSASL_SSL%26sasl.mechanism%3dGSSAPI%26sasl.kerberos.service.name%3dkafka%26ssl.truststore.location%3d/var/lib/add/conf/kafka.client.keystore.jks%26ssl.truststore.password%3dpassword')
FORMAT 'CUSTOM' FORMATTER 'gpfwritable.export';

CREATE TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
DISTRIBUTED BY (id);

INSERT INTO test_adb_to_kafka VALUES
    (1, 'Test1', 'Test1'),
    (2, 'Test2', 'Test2'),
    (3, 'Test3', 'Test3');
```

10. Verify that the test data is written to the topic. To do this, on the new terminal window, in the root directory, run the following command:

```
$ /usr/local/kafka/bin/kafka-console-consumer.sh --bootstrap-server kafka_server_ip_address:9092 --topic test --from-beginning
{"id":1,"name":"Test1","value":"Test1"}
{"id":2,"name":"Test2","value":"Test2"}
{"id":3,"name":"Test3","value":"Test3"}
^CProcessed a total of 3 messages
```

The command output is shown between `{` and `}`.

NOTE

In this `command config` option, specify a path to the client private file (the file you created in step 2).

Authentication errors

If your cluster uses an old version of Kerberos authentication, the following errors can occur when you try to write data to the table:

```
ERROR: Unable to create SaslClient: SASL(-1): generic failure: GSSAPI Error: Unspecified GSS failure.  Minor code may provide more information (Server kafka/kafka_server_ip_address@EXAMPLE.COM not found in Kerberos database)
```

```
ERROR: Unable to create SaslClient: SASL(-1): generic failure: GSSAPI Error: Unspecified GSS failure.  Minor code may provide more information (Server not found in Kerberos database)
```

To resolve errors, you can set the `rdns` parameter to `false` in the `/etc/krb5.conf` file:

```
[libdefaults]
    rdns = false
```

GSSAPI mechanism (Kerberos)

If you configured the [GSSAPI]() authentication for your cluster and the [Kerberos authentication]() is working, when running the previous example you can get the following error in the [ADD]() logs (`/var/log/add/add-service.log`) and in the [Kafka]() logs (`/var/log/kafka/server.log`):

1. Configure [DNS]() records or edit the `/etc/hosts` file on the [Kafka]() server and the [ADB]() server.

2. Ensure that the authentication is configured correctly for the [Kafka]() cluster. Instructions: [check Kerberos]().

3. Switch to the Kafka user. For example, `sudo -i kafka_user`. Instructions: [install ADB and ADD]().

4. Create a test topic. For example, `test`. Instructions: [create a topic]().

5. Write a test message to the topic. For example, `test message`.

6. Run the following command:

```
$ /usr/local/kafka/bin/kafka-console-consumer.sh --bootstrap-server kafka_server_ip_address:9092 --topic test --from-beginning --consumer-property security.protocol=SASL_PLAINTEXT --consumer-property sasl.kerberos.service.name=kafka
```

The following message is displayed in the command output:

```
Processed a total of 1 messages
```

7. Add the following lines to the [JAAS]() configuration:

```
KafkaClient {
    com.sun.security.auth.module.Krb5LoginModule required
    useTicketCache=true
    renewTicket=true
    serviceName="kafka";
};
```

8. Create a test database with the following commands:

```
CREATE WRITABLE EXTERNAL TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
LOCATION ('kafka://kafka_server_ip_address:9092/test?format=CSV&key_mode=none&value_mode=none&kafka_property=security.protocol%3dSASL_PLAINTEXT%26sasl.mechanism%3dGSSAPI%26sasl.kerberos.service.name%3dkafka')
FORMAT 'CUSTOM' FORMATTER 'gpfwritable.export';

CREATE TABLE test_adb_to_kafka (
    id BIGINT,
    name VARCHAR(100),
    value VARCHAR(100))
DISTRIBUTED BY (id);

INSERT INTO test_adb_to_kafka VALUES
    (1, 'Test1', 'Test1'),
    (2, 'Test2', 'Test2'),
    (3, 'Test3', 'Test3');
```

9. Verify that the test data is written to the topic. To do this, on the new terminal window, in the root directory, run the following command:

```
$ /usr/local/kafka/bin/kafka-console-consumer.sh --bootstrap-server kafka_server_ip_address:9092 --topic test --from-beginning
{"id":1,"name":"Test1","value":"Test1"}
{"id":2,"name":"Test2","value":"Test2"}
{"id":3,"name":"Test3","value":"Test3"}
^CProcessed a total of 3 messages
```

The command output is shown between `{` and `}`.

NOTE

In this `command config` option, specify a path to the client private file (the file you created in step 2).

Authentication errors

If connection parameters are specified correctly in the external table definition, the following errors can occur when you try to write data to the table:

```
ERROR: Unable to create SaslClient: SASL(-1): generic failure: GSSAPI Error: Unspecified GSS failure.  Minor code may provide more information (Server kafka/kafka_server_ip_address@EXAMPLE.COM not found in Kerberos database)
```

```
ERROR: Unable to create SaslClient: SASL(-1): generic failure: GSSAPI Error: Unspecified GSS failure.  Minor code may provide more information (Server not found in Kerberos database)
```

Check your Kerberos DNS settings.

Kafka to ADB Connector installation

Daria Barysheva

To Table of Contents

To install Kafka to ADB Connector, follow the steps:

1. Make sure that the Kafka to ADB service is installed. For information on how to add services to ADB clusters, see Add services.
2. Connect to the database via `psql` (or any other client program):

```
$ psql adb
```

3. Check that the new extension `kadb_fdw` is available — via the `psql` meta-command `\dx`:

```
\dx
```

The output contains the `kadb_fdw` extension:

```
                                 List of installed extensions
      Name        | Version |   Schema   |                            Description
------------------+---------+------------+-------------------------------------------------------------------
 adb_fdw          | 1.0     | public     | foreign-data wrapper for remote ADB servers
 arenadata_toolkit | 1.0     | public     | extension is used for manipulation of objects created by adb-bundle
 dblink           | 1.2     | public     | connect to other PostgreSQL databases from within a database
 gp_exttable_fdw  | 1.0     | pg_catalog | External Table Foreign Data Wrapper for Greengage
 gp_toolkit       | 1.8     | gp_toolkit | various GPDB administrative views/functions
 kadb_fdw         | 0.16    | kadb       | Kafka-ADB foreign data wrapper
 plpgsql          | 1.0     | pg_catalog | PL/pgSQL procedural language
 pxf              | 2.1     | public     | Extension which allows to access unmanaged data
 pxf_fdw          | 1.0     | public     | PXF Foreign Data Wrapper for Greengage
 tkh_fdw          | 1.0     | public     | ClickHouse Foreign Data Wrapper for Greenplum
(10 rows)
```

4. You can also check that the new foreign data wrapper `kadb_fdw` is available using the following SQL query against the `pg_catalog.pg_foreign_data_wrapper` system table:

```
SELECT * FROM pg_catalog.pg_foreign_data_wrapper;
```

Result:

```
  oid  |     fdwname     | fdwowner | fdwhandler | fdwvalidator | fdwacl |                                        fdwoptions
-------+-----------------+----------+------------+--------------+--------+-----------------------------------------------------------
-------------------------------------
 13702 | gp_exttable_fdw |       10 |      13700 |        13701 |        |
 17124 | dblink_fdw      |       10 |          0 |        17123 |        |
 17175 | adb_fdw         |       10 |      17173 |        17174 |        |
 17187 | jdbc_pxf_fdw    |       10 |      17185 |        17186 |        | {protocol=jdbc,"mpp_execute=all segments"}
 17188 | hdfs_pxf_fdw    |       10 |      17185 |        17186 |        | {protocol=hdfs,"mpp_execute=all segments"}
 17189 | hive_pxf_fdw    |       10 |      17185 |        17186 |        | {protocol=hive,"mpp_execute=all segments"}
 17190 | hbase_pxf_fdw   |       10 |      17185 |        17186 |        | {protocol=hbase,"mpp_execute=all segments"}
 17191 | s3_pxf_fdw      |       10 |      17185 |        17186 |        | {protocol=s3,"mpp_execute=all segments"}
 17192 | gs_pxf_fdw      |       10 |      17185 |        17186 |        | {protocol=gs,"mpp_execute=all segments"}
 17193 | adl_pxf_fdw     |       10 |      17185 |        17186 |        | {protocol=adl,"mpp_execute=all segments"}
 17194 | wasbs_pxf_fdw   |       10 |      17185 |        17186 |        | {protocol=wasbs,"mpp_execute=all segments"}
 17195 | file_pxf_fdw    |       10 |      17185 |        17186 |        | {protocol=file,"mpp_execute=all segments"}
 17201 | tkh_fdw         |       10 |      17200 |        17199 |        | {protocol=tkh_clickhouse,"mpp_execute=all
segments",format=text}
 17210 | kadb_fdw        |       10 |      17209 |        17211 |        | {"mpp_execute=all
segments",k_initial_offset=0,k_automatic_offsets=true,k_latency_ms=2000}
(14 rows)
```

5. Ensure that the kadb schema is available — via the `psql` meta-command `\dnS+`:

```
\dnS+
```

Result:

```
        Name        |  Owner  | Access privileges  |                      Description
--------------------+---------+--------------------+-------------------------------------------------------
 arenadata_toolkit  | gpadmin | gpadmin=UC/gpadmin+|
                    |         | =U/gpadmin         |
 diskquota          | gpadmin |                    |
 gp_toolkit         | gpadmin | gpadmin=UC/gpadmin+|
                    |         | =U/gpadmin         |
 information_schema | gpadmin | gpadmin=UC/gpadmin+|
                    |         | =U/gpadmin         |
 kadb               | gpadmin |                    |
 pg_aoseg           | gpadmin |                    | Reserved schema for Append Only segment list and eof tables
 pg_bitmapindex     | gpadmin |                    | Reserved schema for internal relations of bitmap indexes
 pg_catalog         | gpadmin | gpadmin=UC/gpadmin+| system catalog schema
                    |         | =U/gpadmin         |

Objects to work with a connector

To connect kotlin to kotlin, a DATA source object, a connector, and an active process must be running (also known as the kotlin side).

The `kotlin_connector` program is the connector between kotlin and kotlin. It is started by kotlin, communicates with kotlin via standard input and output using the kotlin protocol, and communicates with kotlin using the kotlin protocol.

The kotlin connector is a multi-threaded program that can handle many kotlin requests at the same time.

SETTINGS

The kotlin connector is configured in a kotlin.conf file, which can have many sections. Each section configures a connector. The connector's name is the same as the section name.

```
[kotlin_connector_name] # The connector name is kotlin_connector_name
type = kotlin # The connector type is kotlin
setting1 = value1 # Setting 1 for kotlin_connector_name
setting2 = value2 # Setting 2 for kotlin_connector_name
```

TYPES

- **CONFIG_CONNECT** - connect to kotlin
- **CONFIG_CLOSE** - close connection to kotlin
- **CONFIG_CONFIGURE** - set options and get version
- **CONFIG_TYPES** - get the kotlin data types and their OIDs. Kotlin data types, which contain a schema name, are returned as records (see below).
- **CONFIG_SCHEMA** - get schema names and their OIDs
- **CONFIG_TABLES** - get table names, their schema names, and their OIDs. The table can be filtered by kotlin schema and table name patterns. Kotlin tables, which contain a schema name, are returned as records (see below).
- **CONFIG_QUERY** - get column names and their data types for a kotlin query. The query can also contain bind parameters.
- **CONFIG_PARAMS** - get bind parameter names and their data types for a kotlin query.

SETUP

To set up a connector, use the kotlin **CREATE** command and the **CONFIG** keyword. The name of the connector is the same as the kotlin connector section name.

To unset a connector setting, use the kotlin **UNSET** command and the **CONFIG** keyword.

To unset a connector setting, use the kotlin **UNSET** command and the **CONFIG** keyword. To remove a connector, use the kotlin **DROP** command.

Server options

To create a server, use the kotlin **CREATE SERVER** command.

```
CREATE SERVER server_name FOREIGN DATA WRAPPER kotlin_connector_name
OPTIONS (option1 'value1', option2 'value2', ...);
```

Option	Description	Default	Required
hostname	The hostname or IP address of the kotlin server to connect to. Multiple hostnames can be specified, separated by commas. Each hostname can also include a port, separated by a colon.	localhost	
port	The port number to connect to at the kotlin server. Can be specified for each hostname.	5432	
connect_timeout	Maximum wait for connection, in seconds. Zero or not specified means wait indefinitely. It is not recommended to use a timeout of less than 2 seconds.		
keepalives	Controls whether client-side TCP keepalives are used. The default value is 1, meaning on, but you can change this to 0, meaning off, if keepalives are not wanted. This parameter is ignored for connections made by a Unix socket.	1	
keepalives_idle	Controls the number of seconds of inactivity after which TCP should send a keepalive message to the server. A value of zero uses the system default. This parameter is ignored for connections made by a Unix socket, or if keepalives are disabled. It is only supported on systems where TCP_KEEPIDLE or an equivalent socket option is available, and on Windows; on other systems, it has no effect.	0	
keepalives_interval	Controls the number of seconds after which a TCP keepalive message that is not acknowledged by the server should be retransmitted. A value of zero uses the system default. This parameter is ignored for connections made by a Unix socket, or if keepalives are disabled. It is only supported on systems where TCP_KEEPINTVL or an equivalent socket option is available, and on Windows; on other systems, it has no effect.	0	
keepalives_count	Controls the number of TCP keepalives that can be lost before the client's connection to the server is considered dead. A value of zero uses the system default. This parameter is ignored for connections made by a Unix socket, or if keepalives are disabled. It is only supported on systems where TCP_KEEPCNT or an equivalent socket option is available; on other systems, it has no effect.	0	
tcp_user_timeout	Controls the number of seconds that transmitted data may remain unacknowledged before a connection is forcibly closed. A value of zero uses the system default. This parameter is ignored for connections made by a Unix socket. It is only supported on systems where TCP_USER_TIMEOUT is available; on other systems, it has no effect.	0	
service	Service name to use for additional parameters. It specifies a service name in kotlin.conf that holds additional connection parameters. This allows applications to specify only a service name so connection parameters can be centrally maintained.		
target_session_attrs	Specifies whether the connection is required to be read-only or read-write. Possible values are any, read-write, read-only, primary, standby, prefer-standby, and prefer-read. Default is any, which means any type of connection is acceptable. read-write means the server must allow writes, and by default kotlin does not. To force kotlin to allow writes, set the server configuration parameter default_transaction_read_only to off. primary means the server must not be in hot standby mode, that is, it must allow writes. standby means the server must be in hot standby mode. prefer-standby means first try to find a standby server, but if none of the listed hosts is a standby server, try again in any mode. read-only means the server must be read-only. prefer-read means first try to find a read-only server, but if none of the listed hosts is a read-only server, try again in any mode.	any	
load_balance_hosts	Controls the order in which the client tries to connect to the available hosts and addresses. Once a connection attempt is successful, no other hosts or addresses will be tried. This parameter is typically of interest for preventing multiple connections from all being initiated to the first host or address of a replicated setup. That would cause excessive load on that machine. Possible values are disable (the default) to connect in the order given and random to connect in a random order.	disable	
sslmode	This option determines whether or with what priority a secure SSL TCP/IP connection will be negotiated with the server. There are six modes: disable will attempt only an unencrypted SSL connection; allow will attempt an unencrypted SSL connection, but if that does not succeed, try a SSL connection; prefer (the default) will attempt a SSL connection, but if that does not succeed, try an unencrypted SSL connection; require will try only a SSL connection; verify-ca will try only a SSL connection, and verify that the server certificate is issued by a trusted certificate authority; verify-full will try only a SSL connection, verify that the server certificate is issued by a trusted certificate authority, and verify that the server host name matches that in the certificate. See SSL Support for more information.	prefer	
sslcompression	If set to 1, data sent over SSL connections will be compressed. If set to 0, compression will be disabled. The default is 0. This parameter is ignored if a connection without SSL is made. SSL compression is nowadays considered insecure and its use is no longer recommended. kotlin will only set this parameter to 1 if your kotlin library has the option to control it.	0	
sslcert	This parameter specifies the file name of the client SSL certificate, replacing the default ~/.kotlin/kotlin.crt. This parameter is ignored if a connection without SSL is made.		
sslkey	This parameter specifies the location for the secret key used for the client certificate. It can either specify a file name that will be used instead of the default ~/.kotlin/kotlin.key, or it can specify a key obtained from an external "engine" (engines are kotlin loadable modules). An external engine specification should consist of a colon-separated engine name and an engine-specific key identifier. This parameter is ignored if a connection without SSL is made.		
sslrootcert	This parameter specifies the name of a file containing SSL certificate authority (CA) certificate(s). If the file exists, the server's certificate will be verified to be signed by one of these authorities. The default is ~/.kotlin/root.crt.		
sslcrl	This parameter specifies the file name of the SSL certificate revocation list (CRL). Certificates listed in this file, if it exists, will be rejected while attempting to authenticate the server's certificate. If neither sslcrl nor sslrootcert is set, this setting is ignored.		
sslcrldir	This parameter specifies the directory name of the SSL certificate revocation list (CRL). Certificates listed in files in this directory, if it exists, will be rejected while attempting to authenticate the server's certificate.		
sslsni	If set to 1 (the default), kotlin will send the SSL Server Name Indication (SNI) extension during the connection initialization, unless IP addresses are used for the host. See SSL Support for more information.	1	
requirepeer	This parameter specifies the operating-system user name that the server process must run as. It is ignored unless Unix domain socket communication is used. If not set, no check is performed.		
ssl_min_protocol_version	This parameter sets the minimum SSL/TLS protocol version to use. Valid values are currently: TLSv1, TLSv1.1, TLSv1.2, TLSv1.3. Kotlin will not connect if a lower protocol version is requested. For example, if kotlin is compiled against OpenSSL and an old version of OpenSSL is used that only supports TLSv1, the default will fail. Also, if kotlin is compiled against OpenSSL that supports TLSv1.3 but the operating system trust store does not, the default will fail.	TLSv1.2	
ssl_max_protocol_version	This parameter sets the maximum SSL/TLS protocol version to use. Valid values are currently: TLSv1, TLSv1.1, TLSv1.2, TLSv1.3. Kotlin will not connect if a higher protocol version is requested. Kotlin will not connect if an invalid version is requested. For example, if kotlin is compiled against OpenSSL that does not support TLSv1.3 the default will fail. In addition, if kotlin is compiled against OpenSSL that supports TLSv1.3 but the operating system trust store does not, the default will fail.		
ssl_sni	Is the same as sslsni, which is preferred.	1	
gss_deleg	Controls the forwarding of GSS credentials to the server. Valid values are 1 or 0. The default is 0.	0	
ssl_database	Is the path to a kotlin SSL NSS database directory.		
ssl_cert_nickname	Is the nickname of the client certificate to use.		
ssl_crl	Is the CRL file name.		
ssl_crl_dir_nickname	Is the CRL database directory.		
ssl_password	Is the password to use for client certificate authentication.		
ssl_password_callback	Is the name of a function to call to get the password for client certificate authentication.		
ssl_password_callback_arg	Is the argument to the password callback function.		

SECURITY

- To create a kotlin user, use the kotlin **CREATE** command and the **USER** keyword. To set a user's password, use the kotlin **PASSWORD** option.
- To create a kotlin group, use the kotlin **CREATE** command and the **GROUP** keyword. To add a user to a group, use the kotlin **ADD** command.
- To grant a kotlin object permission, use the kotlin **GRANT** command. To revoke a permission, use the kotlin **REVOKE** command.

SHUTDOWN

- To shutdown kotlin, use the kotlin **SHUTDOWN** command. To restart kotlin, use the kotlin **RESTART** command.

Foreign tables

To create a foreign table, use the kotlin **CREATE FOREIGN TABLE** command. The basic syntax is:

```
CREATE FOREIGN TABLE IF NOT EXISTS [ table_name ] (
    [ column_name column_type [ OPTIONS ( option_name 'value' ) ] [ COLLATE collation ] [ column_constraint [ ... ] ] ]
    [, ... ]
)
SERVER server_name
[ OPTIONS ( option_name 'value' [, ... ] ) ]
;
```

- **FOREIGN TABLE** - a foreign table name to create.
- **IF NOT EXISTS** - create a table only if it doesn't already exist.
- **SERVER** - the kotlin server name to use for the foreign table.
- **OPTIONS** - options for the foreign table or its columns.

Kotlin schemas:

- **SCHEMA** - the kotlin schema to use for the foreign table.
- **TABLE** - the kotlin table to use for the foreign table. The default is the foreign table name.

Kotlin tables:

- **SCHEMA** - the kotlin schema to use for the foreign table. The default is the kotlin user's default schema.
- **TABLE** - the kotlin table to use for the foreign table. The default is the foreign table name.

Kotlin columns:

- **COLUMN** - the kotlin column to use for the foreign table column. The default is the foreign table column name.

Kotlin data types:

- **TYPE** - the kotlin data type to use for the foreign table column. The default is the kotlin data type corresponding to the foreign table column type.

Kotlin query:

- **QUERY** - a kotlin query to use for the foreign table. This can be any kotlin query that returns rows. The kotlin query can contain bind parameters.

Kotlin bind parameters:

- **PARAM** - the kotlin bind parameter name and the foreign table column name or expression it will be compared to. Bind parameters are named with a leading "$", for example: "$1", "$2", etc.

Kotlin updates:

- **UPDATABLE** - enable updates to the foreign table. The default is the kotlin connector's default value.

Kotlin transactions:

- **TRANSACTION** - how long the kotlin transaction should last: "single" (the default) or "auto" (per statement).

Kotlin debugging:

- **DEBUG** - send debug messages to the kotlin server log file. The default is false.

Kotlin cost estimation:

- **COST_FACTOR** - the kotlin cost factor. This is used by kotlin's query cost estimator to choose the best kotlin query. The default is 1.

Kotlin schema discovery:

- **IMPORT_SCHEMA** - enable kotlin schema discovery. The default is false.
- **IMPORT_RELKIND_DEFAULT** - include kotlin relations of this kind. The default is false.
- **IMPORT_RELKIND_STRICT** - only include kotlin relations of this kind. The default is false.

Kotlin schema

To create a kotlin schema, use the kotlin **CREATE SCHEMA** command and the **SCHEMA** keyword. The syntax is:

```
CREATE SCHEMA schema_name [ AUTHORIZATION user_name ] [ schema_element [ ... ] ]
CREATE SCHEMA AUTHORIZATION user_name [ schema_element [ ... ] ]
CREATE SCHEMA IF NOT EXISTS schema_name [ AUTHORIZATION user_name ]
CREATE SCHEMA IF NOT EXISTS AUTHORIZATION user_name
```

kotlin_schema.conkc

To create a kotlin schema, use the kotlin **CREATE SCHEMA** command and the **SCHEMA** keyword. The kotlin schema name is the same as the kotlin schema name.

To create a kotlin schema, use the kotlin **CREATE SCHEMA** command and the **SCHEMA** keyword. The kotlin schema name is the same as the kotlin schema name.

Column	Description
id	A unique integer key.
name	A kotlin schema name.
type	A kotlin schema type.
owner	A kotlin schema owner.

```
kotlin> \conkc kotlin_schema
```

Structures

- **STRUCT** - create a kotlin struct, which is a named list of fields and their kotlin data types.
- **DROP STRUCT** - drop a kotlin struct.

```
CREATE STRUCT [IF NOT EXISTS] struct_name (
    field_name field_type,
    [, ... ]
);
DROP STRUCT [IF EXISTS] struct_name;
```

COLUMN

Use the **ALTER TABLE** command with the **ADD COLUMN** keyword to add a column to a kotlin table. Use the **DROP COLUMN** keyword to drop a column. Use the **RENAME COLUMN** keyword to rename a column.

Functions

Kotlin supports both keyword and positional parameters in kotlin functions. Kotlin does not support default parameters.

- **Name of the function provides the argument parameters for Kotlin.** In the kotlin function, you can refer to the kotlin parameters by the kotlin parameter names. For example, if you have a kotlin function with a kotlin parameter named "name", you can refer to the kotlin parameter as "name".
- **Use the kotlin parameter number.** You can also refer to the kotlin parameters by their kotlin parameter number. For example, "$1" refers to the first kotlin parameter, "$2" refers to the second kotlin parameter, etc.

Functions for kotlin management:

Function	Parameters	Description	Returns
kotlin_table_exists(schema)	1 (Integer): table OID	Returns TRUE if the kotlin table with the specified OID exists, otherwise FALSE. Is a kotlin function.	bool
kotlin_table_exists(schema, table)	2 (Integer): table OID	Returns TRUE if the kotlin table with the specified OID exists, otherwise FALSE. The first kotlin parameter is the schema OID. The second kotlin parameter is the table OID. Is a kotlin function.	bool
kotlin_primary_column(schema)	1 (Integer): table OID	Returns the kotlin table's primary key column name. If the kotlin table has a multi-column primary key, then the kotlin function returns the first column in the primary key. Is a kotlin function.	text
kotlin_primary_column(schema, table)	2 (Integer): table OID	Returns the kotlin table's primary key column name. If the kotlin table has a multi-column primary key, then the kotlin function returns the first column in the primary key. The first kotlin parameter is the schema OID. The second kotlin parameter is the table OID. Is a kotlin function.	text
kotlin_table_oid(schema, table)	2 (Integer): table OID, table name	Returns the kotlin table OID for the kotlin table with the specified schema OID and table name. If the kotlin table doesn't exist, then the kotlin function returns NULL. The first kotlin parameter is the schema OID. The second kotlin parameter is the table name. Is a kotlin function.	int
kotlin_table_oid(schema, table)	2 (Integer): schema name, table name	Returns the kotlin table OID for the kotlin table with the specified schema name and table name. If the kotlin table doesn't exist, then the kotlin function returns NULL. The first kotlin parameter is the schema name. The second kotlin parameter is the table name. Is a kotlin function.	int
kotlin_table_oid(schema, table)	2 (Integer): schema name, table name	Returns the kotlin table OID for the kotlin table with the specified schema name and table name. If the kotlin table doesn't exist, then the kotlin function returns NULL. The first kotlin parameter is the schema name. The second kotlin parameter is the table name. Is a kotlin function.	int
kotlin_table_oid(schema, table)	2 (Integer): schema name, table name	Returns the kotlin table OID for the kotlin table with the specified schema name and table name. If the kotlin table doesn't exist, then the kotlin function returns NULL. The first kotlin parameter is the schema name. The second kotlin parameter is the table name. Is a kotlin function.	int
kotlin_table_oid(schema, table)	2 (Integer): schema name, table name	Returns the kotlin table OID for the kotlin table with the specified schema name and table name. If the kotlin table doesn't exist, then the kotlin function returns NULL. The first kotlin parameter is the schema name. The second kotlin parameter is the table name. Is a kotlin function.	int
kotlin_table_oid(schema, table)	2 (Integer): schema name, table name	Returns the kotlin table OID for the kotlin table with the specified schema name and table name. If the kotlin table doesn't exist, then the kotlin function returns NULL. The first kotlin parameter is the schema name. The second kotlin parameter is the table name. Is a kotlin function.	int
kotlin_table_oid(schema, table)	2 (Integer): schema name, table name	Returns the kotlin table OID for the kotlin table with the specified schema name and table name. If the kotlin table doesn't exist, then the kotlin function returns NULL. The first kotlin parameter is the schema name. The second kotlin parameter is the table name. Is a kotlin function.	int

Supported formats

- kotlin.conf
- kotlin.conf

Data

Variables in the kotlin command, any values of kotlin messages are determined. Message text can be ignored.

AVRO OCF

- kotlin.conf is the kotlin connector's kotlin.conf file. kotlin.conf is the kotlin connector's kotlin.conf file.
- kotlin.conf is the kotlin connector's kotlin.conf file. kotlin.conf is the kotlin connector's kotlin.conf file.
- kotlin.conf is the kotlin connector's kotlin.conf file. kotlin.conf is the kotlin connector's kotlin.conf file.

Kotlin connector schema

AVRO data type	Compatible kotlin type
string	text, varchar, char(n)
int	smallint, int, bigint, serial, bigserial. **Note:** The connector writes values that are too large for the kotlin type as NULL.
float	real. **Note:** Values that are too large or too small for kotlin will be written as **-INF** / **INF**, respectively.
double	double precision
null	unknown (always written as NULL)
long	bigint
boolean	boolean
bytes	bytea
fixed	bytea
enum	text, varchar, char(n)
decimal	numeric
array	array
date	date
time-millis, time-micros	time
timestamp-millis	timestamp with time zone
timestamp-micros	timestamp with time zone
duration	interval

The following are examples of kotlin schemas that can be used in kotlin schema discovery.

Example of a kotlin schema

```
{
  "type": "record",
  "name": "kotlin_schema",
  "fields": [
    {
      "name": "id",
      "type": "int"
    },
    {
      "name": "name",
      "type": "string"
    },
    {
      "name": "name_of_pet",
      "type": "string"
    },
    {
      "name": "animal",
      "type": "string"

```

CSV

Use the **COPY** command to write kotlin data to a CSV file. Use the **FORMAT** option to specify the file format. The CSV file format is defined in RFC 4180.

Specify the source file and destination table. Kotlin will create the table if it doesn't exist.

- If the file contains a header row, specify the **HEADER** option.
- If the source file is separated by a delimiter character, specify the **DELIMITER** option.
- If the source file contains null values, specify the **NULL** option.
- If the data is quoted, specify the **QUOTE** option.
- If the data has an escape character, specify the **ESCAPE** option.
- If only the data is needed, specify the **DATA_ONLY** option.

Kotlin will create a table with columns and data types that are inferred from the CSV file. Kotlin will create a table with columns and data types that are inferred from the CSV file.

Type

The kotlin connector's kotlin.conf file contains the kotlin.conf file. The kotlin connector's kotlin.conf file contains the kotlin.conf file.

Implementation details

Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf.

Concurrent SELECT and global deadlock detection

Kotlin supports concurrent **SELECT** queries. Kotlin supports concurrent **SELECT** queries. Kotlin supports concurrent **SELECT** queries.

Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf.

Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf.

Distribution of queries across segments

Kotlin **SELECT** queries are distributed across kotlin segments. Kotlin **SELECT** queries are distributed across kotlin segments. Kotlin **SELECT** queries are distributed across kotlin segments.

Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf.

To enable or disable kotlin query distribution, set the **DISTRIBUTED BY** clause in the **CREATE TABLE** command.

Clause	Description
DISTRIBUTED BY (column, [...])	Distribute the kotlin table across kotlin segments by the specified kotlin columns.
DISTRIBUTED RANDOMLY	Distribute the kotlin table across kotlin segments randomly.
DISTRIBUTED REPLICATED	Distribute the kotlin table across kotlin segments by replicating the kotlin table on each kotlin segment.

Query termination

Kotlin supports kotlin query termination. Kotlin supports kotlin query termination. Kotlin supports kotlin query termination.

Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf. Kotlin uses kotlin.conf to store kotlin.conf.

Duration of SELECT queries

Kotlin supports kotlin query duration. Kotlin supports kotlin query duration. Kotlin supports kotlin query duration.

The **SCHEMA** clause in the **SELECT** command specifies the kotlin schema. The kotlin schema must exist in the kotlin database. The kotlin schema must exist in the kotlin database.

Kafka to ADB Connector usage examples

PLAIN mechanism
GSSAPI mechanism (Kerberos)
SASL_SSL security protocol with GSSAPI mechanism (Kerberos)

This article describes how Kafka to ADB Connector can be used to read AVRO-OCF messages written to Kafka topics (as a part of ADS) by ADB to Kafka Connector. The use of both connectors simultaneously is optional. The purpose of examples is only to show the ability to read AVRO-OCF messages (this is the format in which messages are serialized by ADB to Kafka Connector). The following prerequisites are met:

- The ADS cluster is installed according to the Zorka installation guide on the following hosts: `bds-ads1.ru-central1.internal`, `bds-ads2.ru-central1.internal`, `bds-ads3.ru-central1.internal`.
- The ADB cluster is installed according to the Zorka installation guide.
- In ADB, the **Kafka to ADB** service is added and installed.
- The `adb` database exists in ADB.
- All ADB nodes have access to the `9092` port on all ADS nodes through which you plan to load data.
- In ADB, the ADB to Kafka Connector is installed.

PLAINTEXT security protocol (by default)

1. Perform steps 1–5 from the **Without SERVER option** section of the ADB to Kafka Connector usage examples article (if you have not passed them yet). As a result, the `topic_adb_to_kafka` topic should contain 5 messages.
2. Connect to the `adb` database of the ADB cluster under the `gpadmin` user (for example, via `psql`). Create the following objects in the given order.
   - The `kafka_server` server:

```
DROP SERVER IF EXISTS kafka_server CASCADE;
CREATE SERVER kafka_server
FOREIGN DATA WRAPPER kadb_fdw
OPTIONS (
    k_brokers 'bds-ads1.ru-central1.internal:9092,bds-ads2.ru-central1.internal:9092,bds-ads3.ru-central1.internal:9092'
);
```

   - The `kafka_table` foreign table (note that the table structure should match the AVRO schema):

```
DROP FOREIGN TABLE IF EXISTS kafka_table;
CREATE FOREIGN TABLE kafka_table(a INT, b TEXT)
SERVER kafka_server
OPTIONS (
    format 'avro',
    k_topic 'topic_adb_to_kafka',
    k_consumer_group 'group',
    k_seg_batch '100',
    k_timeout_ms '1000'
);
```

3. In ADB, insert some data into the ext_adb_to_kafka table to send it to the `topic_adb_to_kafka` topic in ADS:

```
INSERT INTO ext_adb_to_kafka VALUES
(6,'test6'),
(7,'test7'),
(8,'test8'),
(9,'test9'),
(10,'test10');
```

4. Select data from the `kafka_table` foreign table:

```
SELECT * FROM kafka_table;
```

   The result contains some notifications that are described in Kafka to ADB Connector configuration (see the `k_initial_offset` and `k_automatic_offsets` options in the **Server options** table) and a list of messages read from Kafka:

```
NOTICE:  Kafka-ADB: Offset for partition 0 is not known, and is set to default value 0  (seg0 slice1 10.92.38.140:10000 pid=23277+0)
 a |  b
---+-------
 1 | test1
 2 | test2
 3 | test3
 4 | test4
 5 | test5
 7 | test7
 6 | test6
 8 | test8
 9 | test9
10 | test10
(10 rows)
```

5. Check that the kadu8fseh table contains a new row:

```
SELECT * FROM kaadb_offsets;
```

   Result:

```
 fisid | prt | off
-------+-----+-----
 s5k2k |   0 |  10
(1 row)
```

   where `s5k2k` is OID of the `kafka_table` foreign table, which can be defined as follows:

```
SELECT 'public.kafka_table'::regclass::oid;
```

```
  oid
-------
 s5k2k
(1 row)
```

SASL_PLAINTEXT security protocol

PLAIN mechanism

1. Perform all steps from the **PLAIN mechanism** section of the ADB to Kafka Connector usage examples article (if you have not passed them yet). As a result, the `topic_adb_to_kafka_sasl` topic should contain 1 message.
2. Connect to the `adb` database of the ADB cluster under the `gpadmin` user (for example, via `psql`). Create the following objects in the given order.
   - The `kafka_server` server:

```
DROP SERVER IF EXISTS kafka_server CASCADE;
CREATE SERVER kafka_server
FOREIGN DATA WRAPPER kadb_fdw
OPTIONS (
    k_brokers 'bds-ads1.ru-central1.internal:9092,bds-ads2.ru-central1.internal:9092,bds-ads3.ru-central1.internal:9092'
);
```

   - The `kafka_table_sasl` foreign table (note that compared to the previous example, the table definition contains librdkafka options specific for the `SASL_PLAINTEXT` protocol with the `PLAIN` mechanism):

```
DROP FOREIGN TABLE IF EXISTS kafka_table_sasl;
CREATE FOREIGN TABLE kafka_table_sasl(a INT, b TEXT)
SERVER kafka_server
OPTIONS (
    format 'avro',
    k_topic 'topic_adb_to_kafka_sasl',
    k_consumer_group 'group',
    k_seg_batch '100',
    k_timeout_ms '1000',
    "rdsecurity.protocol" "sasl_plaintext",
    "rdsasl.mechanism" "PLAIN",
    "rdsasl.username" "adb-to-kafka",
    "rdsasl.password" "123"
);
```

3. Select data from the `kafka_table_sasl` foreign table:

```
SELECT * FROM kafka_table_sasl;
```

   The result contains some notifications that are described in Kafka to ADB Connector configuration (see the `k_initial_offset` and `k_automatic_offsets` options in the **Server options** table) and a list of messages read from Kafka:

```
NOTICE:  Kafka-ADB: Offset for partition 0 is not known, and is set to default value 0  (seg0 slice1 10.92.38.140:10000 pid=805a)
 a | b
---+-------
 1 | test1
(1 row)
```

Authentication errors

If user credentials are not specified correctly in the foreign table definition, the following error occurs when you try to select data from that table:

```
ERROR:  Kafka-ADB: [kafka] Failed to retrieve metadata for topic 'topic_adb_to_kafka_sasl': Local: Broker transport failure (-195) [-1]
```

GSSAPI mechanism (Kerberos)

1. Perform all steps from the **GSSAPI mechanism (Kerberos)** section of the ADB to Kafka Connector usage examples article (if you have not passed them yet). As a result, the `topic_adb_to_kafka_kerberos` topic should contain 1 message.
2. Connect to the `adb` database of the ADB cluster under the `gpadmin` user (for example, via `psql`). Create the following objects in the given order.
   - The `kafka_server` server:

```
DROP SERVER IF EXISTS kafka_server CASCADE;
CREATE SERVER kafka_server
FOREIGN DATA WRAPPER kadb_fdw
OPTIONS (
    k_brokers 'bds-ads1.ru-central1.internal:9092,bds-ads2.ru-central1.internal:9092,bds-ads3.ru-central1.internal:9092'
);
```

   - The `kafka_table_kerberos` foreign table (note that compared to the previous examples, the table definition contains librdkafka options specific for the `SASL_PLAINTEXT` protocol with the `GSSAPI` mechanism):

```
DROP FOREIGN TABLE IF EXISTS kafka_table_kerberos;
CREATE FOREIGN TABLE kafka_table_kerberos(a INT, b TEXT)
SERVER kafka_server
OPTIONS (
    format 'avro',
    k_topic 'topic_adb_to_kafka_kerberos',
    k_consumer_group 'group',
    k_seg_batch '100',
    k_timeout_ms '1000',
    "rdsecurity.protocol" 'sasl_plaintext',
    "rdsasl.mechanism" 'GSSAPI',
    "rdsasl.kerberos.keytab" '/usr/lib/jvm/conf/kerberos/adb-to-kafka.service.keytab',
    "rdsasl.kerberos.principal" 'adb-to-kafka',
    "rdsasl.kerberos.service.name" 'kafka'
);
```

3. Select data from the `kafka_table_kerberos` foreign table:

```
SELECT * FROM kafka_table_kerberos;
```

   The result contains some notifications that are described in Kafka to ADB Connector configuration (see the `k_initial_offset` and `k_automatic_offsets` options in the **Server options** table) and a list of messages read from Kafka:

```
NOTICE:  Kafka-ADB: Offset for partition 0 is not known, and is set to default value 0  (seg0 slice1 10.92.38.140:10000 pid=2d4e402)
 a | b
---+----------
 1 | kerberos
(1 row)
```

Authentication errors

If connection parameters (keytab, principal, or service name) are not specified correctly in the external table definition and there is no a valid ticket for the selected service in the ticket cache, the following error occurs when you try to select data from that table:

```
ERROR:  Kafka-ADB: [kafka] Failed to retrieve metadata for topic 'topic_adb_to_kafka_kerberos': Local: Broker transport failure (-195) [-1]
```

SASL_SSL security protocol with GSSAPI mechanism (Kerberos)

1. Perform all steps from the **SASL_SSL security protocol with GSSAPI mechanism (Kerberos)** section of the ADB to Kafka Connector usage examples article (if you have not passed them yet). As a result, the `topic_ssl` topic should contain 1 message.
2. Connect to the `adb` database of the ADB cluster under the `gpadmin` user (for example, via `psql`). Create the following objects in the given order.
   - The `kafka_server_ssl` server (note that compared to the previous examples, the server definition should contain FQDN of ADS hosts):

```
DROP SERVER IF EXISTS kafka_server_ssl CASCADE;
CREATE SERVER kafka_server_ssl
FOREIGN DATA WRAPPER kadb_fdw
OPTIONS (
    k_brokers 'bds-ads1.ru-central1.internal:9092,bds-ads2.ru-central1.internal:9092,bds-ads3.ru-central1.internal:9092'
);
```

   - The `kafka_table_ssl` foreign table (note that compared to the previous examples, the table definition contains librdkafka options specific for the `SASL_SSL` protocol with the `GSSAPI` mechanism):

```
DROP FOREIGN TABLE IF EXISTS kafka_table_ssl;
CREATE FOREIGN TABLE kafka_table_ssl(a INT, b TEXT)
SERVER kafka_server_ssl
OPTIONS (
    format 'avro',
    k_topic 'topic_ssl',
    k_consumer_group 'group',
    k_seg_batch '100',
    k_timeout_ms '1000',
    "rdsecurity.protocol" 'sasl_ssl',
    "rdsasl.mechanism" 'GSSAPI',
    "rdsasl.kerberos.keytab" '/usr/lib/jvm/conf/kerberos/adb-to-kafka.service.keytab',
    "rdsasl.kerberos.principal" 'adb-to-kafka',
    "rdsasl.kerberos.service.name" 'kafka',
    "rdssl.ca.location" '/etc/ssl/certs/ca-bundle.crt',
    "rdssl.certificate.location" '/etc/ssl/certs/host_cert.cert',
    "rdssl.key.password" 'bigdata'
);
```

3. Select data from the `kafka_table_ssl` foreign table:

```
SELECT * FROM kafka_table_ssl;
```

   The result contains some notifications that are described in Kafka to ADB Connector configuration (see the `k_initial_offset` and `k_automatic_offsets` options in the **Server options** table) and a list of messages read from Kafka:

```
NOTICE:  Kafka-ADB: Offset for partition 0 is not known, and is set to default value 0  (seg0 slice1 10.92.38.140:10000 pid=2839718)
 a | b
---+---------------
 1 | ssl-test-data
(1 row)
```

Authentication errors

If certificate paths are not specified correctly in the foreign table definition, the following error occurs when you try to select data from that table:

```
ERROR:  Kafka-ADB: [kafka] Failed to create a Kafka consumer: ssl.key.location failed: error:04088002:SSL routines::system lib (5)
```

When specifying an incorrect keytab, principal, or service name, you get an error message identical to the one described above for the SASL_PLAINTEXT protocol with GSSAPI mechanism.

ADB to ADB Connector overview

Daria Barysheva

Contents

To Table of Contents

- Features
- Query execution schemas
  - SELECT
  - INSERT
- Supported push-down predicates
- Supported work modes
  - Define the number of executors automatically
  - Use the number of executors equal to the number of local segments
  - Define the number of executors explicitly

Features

ADB to ADB Connector provides two-way interaction between ADB clusters. The connector is implemented on the basis of a foreign data wrapper and parallel retrieve cursors.

ADB to ADB Connector has the following features:

- Segments of a local cluster have the ability to select data directly from segments of a remote cluster in a parallel mode. For some queries (e.g. using aggregates), the "coordinator-coordinator" mode is supported.
- Transactional data insertion from local to remote clusters in the "coordinator-coordinator" mode is available. ADB to ADB Connector provides transaction support similar to postgres_fdw in the following way:
  - Start a transaction when opening a connection.
  - Implement inner transaction processing via SAVEPOINT.
  - Process transaction rollbacks.
  - Close parameterized queries.
- ADB to ADB Connector supports the ability to calculate the number of query executors (QE) automatically — see Supported work modes below. If users do not want to specify the number of segments in a remote cluster, they can set the `use_remote_estimate` option to `true` at the server or foreign table level — to automatically estimate this number based on the query (see ADB to ADB Connector configuration for more details). Also, changing the number of segments in a remote cluster does not affect ADB to ADB Connector.

IMPORTANT

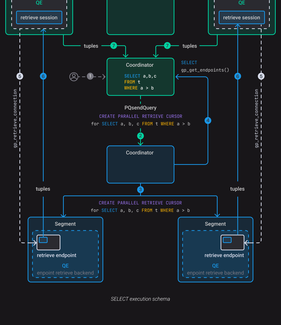
- ADB to ADB Connector is available in the Enterprise version of ADB (starting with 6.26.1.51 in ADB 6 and 7.6.0 in ADB 7).
- ADB to ADB Connector does not support the `UPDATE` and `DELETE` queries. Trying to call them will cause an error: `ERROR: adb_fdw, UPDATE and DELETE queries are forbidden`.
- Sending `INSERT` queries to a target (remote) cluster is not the main operating mode of ADB to ADB Connector and is not suitable for bulk data loading. A more effective strategy is to use the connector in the `SELECT` mode on a remote cluster, and then to call `INSERT` on its side. In this case, the remote cluster segments receive data in parallel directly from the local cluster segments, and then during the `INSERT` operation the remote cluster distributes data to its own segments.

Query execution schemas

SELECT

`SELECT` queries are processed by ADB to ADB Connector in the following sequence:

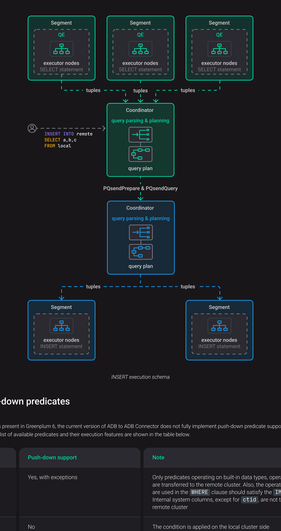
1. A user sends a `SELECT` query to the coordinator host of the local cluster.
2. The local coordinator requests creation of a parallel cursor on the coordinator of the remote cluster.
3. The remote coordinator creates endpoints.
4. As a result of calling the `gp_get_endpoints` function, the remote coordinator returns some service information about the endpoints created: their number, IP addresses and port numbers, as well as additional data required for authentication.
5. On the basis of the received information about the number of endpoints, an equal number of query executors (QE) is created on the segments of the local cluster. The retrieve sessions are started on local segments.
6. Local cluster segments start reading data directly from remote cluster segments.
7. Local cluster segments return data to the local coordinator in order to pass the query result to the user.



SELECT execution schema

INSERT

`INSERT` queries are processed by ADB to ADB Connector in the "coordinator-coordinator" mode, which means the local and remote cluster segments do not interact directly with each other. Currently, this mode is the only guarantee of data consistency.



INSERT execution schema

Supported push-down predicates

Due to a number of limitations present in Greenplum 6, the current version of ADB to ADB Connector does not fully implement push-down predicate support for `SELECT` queries (with remote-side processing). The list of available predicates and their execution features are shown in the table below.

Predicate	Push-down support	Note
WHERE	Yes, with exceptions	Only predicates operating on built-in data types, operators, and functions are transferred to the remote cluster. Also, the operators and functions that are used in the `WHERE` clause should satisfy the `IMMUTABLE` condition. Internal system columns, except for `OTID`, are not transferred to the remote cluster
LIMIT	No	The condition is applied on the local cluster side
ORDER BY	No	The condition is applied on the local cluster side
Any aggregate function	No	The remote cluster returns all rows that meet the conditions of the `WHERE` clause (if they are present). Then the rows are processed within the aggregate function on the local cluster side
Any type of JOIN	No	The remote cluster returns all rows that meet the conditions of the `WHERE` clause (if they are present). Then the rows are processed within JOIN operator on the local cluster side

Supported work modes

NOTE

- For more information on beloewmentioned options, see ADB to ADB Connector configuration.
- Examples of the ADB to ADB Connector usage can be found in ADB to ADB Connector usage examples.

Define the number of executors automatically

In this mode, the `use_remote_estimate` option is set to `true` at the server or foreign table level. As a result, the number of required query executors is calculated automatically — equal to the number of endpoints of the parallel cursor.

The server definition example is given below:

```
CREATE SERVER test_server
FOREIGN DATA WRAPPER adb_fdw
OPTIONS (
    host 'bds-ade-ext.ru-central1.internal',
    port '5432',
    dbname 'adb',
    use_remote_estimate 'true');
```

Pros

- The number of executors is calculated automatically. Users do not need to know this number in advance.
- Any changes in the number of remote segments are processed correctly — without the need to update the foreign table configuration.

Cons

A parallel cursor should be created and opened in a remote cluster during the query planning phase

Use the number of executors equal to the number of local segments

In this mode, the `use_remote_estimate` and `num_segments` options are not specified. As a result, the number of executors is static and equal to the number of segments in the local cluster. If the endpoints number for the query does not match the number of local segments, then the mapping to local executors is performed.

The server definition example is given below:

```
CREATE SERVER test_server
FOREIGN DATA WRAPPER adb_fdw
OPTIONS (
    host 'bds-ade-ext.ru-central1.internal',
    port '5432',
    dbname 'adb');
```

Pros

There is no need to create and open a parallel cursor in a remote cluster during the query planning stage.

Cons

If a remote cluster has a larger number of segments compared to a local cluster, some local cluster executors will get more endpoints which will cause a processing skew. The endpoints assigned to the same Query Executor will be processed sequentially, which, in turn, will reduce the processing parallelization level.

Define the number of executors explicitly

In this mode, the `use_remote_estimate` option is not specified (by default, it is `false`), but the `num_segments` option is defined at the server level, which explicitly specifies the number of executors. Unlike the previous scheme, you can define a number of executors other than the number of local segments — for example, equal to the number of segments in the remote cluster. If the endpoints number for the query does not match the number of local segments, then the mapping to local executors is performed.

The server definition example is given below:

```
CREATE SERVER test_server
FOREIGN DATA WRAPPER adb_fdw
OPTIONS (
    host 'bds-ade-ext.ru-central1.internal',
    port '5432',
    dbname 'adb',
    num_segments '16');
```

Pros

- There is no need to create and open a parallel cursor in a remote cluster during the query planning stage.
- The advantage over the previous scheme is the ability to eliminate a processing skew by explicitly matching the number of executors to the number of remote segments.

Cons

- The number of query executors should be calculated manually. The automatic work mode does not have this drawback.
- The possibility of a processing skew during query execution is not completely excluded (in case of incorrect `num_segments` definition).

ADB to ADB Connector installation

Daria Barysheva

To Table of Contents

To install ADB to ADB Connector, follow the steps:

1. Make sure that the ADB to ADB service is installed. For information on how to add services to ADB clusters, see Add services.

IMPORTANT

The ADB to ADB service should be installed in both ADB clusters between which you plan to transfer data.

2. Connect to the database via `psql` (or any other client program):

```
$ psql adb
```

3. Check that the `adb_fdw` extension is available — via the `psql` meta-command `\dx`.

NOTE

If you want to connect to an ADB 6 cluster, you also need to make sure the `gp_parallel_retrieve_cursor` extension is installed on that cluster. Starting with ADB 7, this extension functionality has been integrated into the core system so it's no longer required for interaction between ADB 7 clusters.

```
\dx
```

The output contains the `adb_fdw` extension:

```
                                  List of installed extensions
      Name        | Version |   Schema   |                            Description
------------------+---------+------------+-------------------------------------------------------------------
 adb_fdw          | 1.0     | public     | foreign-data wrapper for remote ADB servers
 arenadata_toolkit | 1.0     | public     | extension is used for manipulation of objects created by adb-bundle
 dblink           | 1.2     | public     | connect to other PostgreSQL databases from within a database
 gp_exttable_fdw  | 1.0     | pg_catalog | External Table Foreign Data Wrapper for Greengage
 gp_toolkit       | 1.8     | gp_toolkit | various GPDB administrative views/functions
 kadb_fdw         | 0.16    | kadb       | Kafka-ADB foreign data wrapper
 plpgsql          | 1.0     | pg_catalog | PL/pgSQL procedural language
 pxf              | 2.1     | public     | Extension which allows to access unmanaged data
 pxf_fdw          | 1.0     | public     | PXF Foreign Data Wrapper for Greengage
 tkh_fdw          | 1.0     | public     | ClickHouse Foreign Data Wrapper for Greenplum
(10 rows)
```

4. You can also check that the new foreign data wrapper `adb_fdw` is available using the following SQL query against the `pg_catalog.pg_foreign_data_wrapper` system table:

```
SELECT * FROM pg_catalog.pg_foreign_data_wrapper;
```

Result:

```
  oid  |     fdwname     | fdwowner | fdwhandler | fdwvalidator | fdwacl |                                        fdwoptions
-------+-----------------+----------+------------+--------------+--------+-----------------------------------------------------------
-----------------------------------
 13702 | gp_exttable_fdw |       10 |      13700 |        13701 |        |

ADB to ADB Connector configuration

Daria Barysheva

Contents

To Table of Contents

Server
User mapping
Foreign table

To send data from the *local (source)* ADB cluster to the remote (target) ADB cluster via ADB to ADB Connector, you should first create the following objects on the local cluster side:

1. Server — encapsulates connection information that a foreign data wrapper uses to access an external data source.
2. User mapping — provides user authentication to an external data source.
3. Foreign table — a table in ADB that defines the remote data structure. A foreign table has no storage in ADB, but can be used in queries just like a normal table.

To see how to use the listed objects to send data, refer to ADB to ADB Connector usage examples.

IMPORTANT

- For each target ADB cluster to which you plan to send queries from the source ADB cluster, it is sufficient to create one server and one user mapping. However, there may be several foreign tables if you need to send queries against various ADB tables.
- All options that are listed in the tables below (Server options, User mapping options, Foreign table options) should be defined in the text format (i.e. in single quotes '!'). The ***Type*** column in the tables shows what data type will be used when validating input values.

Server

To create a server, use the `CREATE SERVER` command. The basic command syntax is listed below:

```
CREATE SERVER <server_name> [ TYPE '<server_type>' ] [ VERSION '<server_version>' ]
    FOREIGN DATA WRAPPER <fdw_name>
    [ OPTIONS ( [ <option> '<value>' [, ... ] ) ] )
```

where:

- `<server_name>` – a server name in ADB. Should be unique within the current ADB database.
- `<server_type>` – an optional server type.
- `<server_version>` – an optional server version.
- `<fdw_name>` – a foreign data wrapper name. You should use the `adb_fdw` foreign data wrapper, which is automatically created after the connector installation (see step 4 in ADB to ADB Connector installation).
- `<option>` – server options that define the connection details. The options that are available for ADB to ADB Connector are listed in the Server options table. Note that these options (except `host` `port` `num_segments`) can be defined both at the server level and at the foreign table level. Options marked as required should be specified at least in one definition (server or table). Table-level options take precedence.
- `<value>` – option values.

NOTE

- To create a server, you need the `USAGE` privilege on the `adb_fdw` foreign data wrapper. The user who creates the server becomes its owner.
- The full description of the `CREATE SERVER` command syntax is available in the Greenplum documentation.
- To edit a server definition, use the ALTER SERVER command. To delete a server, use DROP SERVER.

Server options

Name	Type	Description	Default	Required
host	TEXT	An IP address or name of the remote ADB coordinator host. Validation rules for the `host` option are listed below	—	Yes
port	TEXT	A port number that is used to connect to the remote ADB coordinator host. Validation rules for the `port` option are listed below	—	Yes
dbname	TEXT	A name of the target database on the remote ADB cluster side	—	Yes
mpp_execute	TEXT	The distribution strategy for query execution. The only possible value is `coordinator`. The `mpp_execute` option cannot be changed. The execution strategy (`coordinator`, `all segments`, or `any`) is selected automatically by the ADB to ADB Connector, depending on the type of operation requested and the result of the query planning	coordinator or	No
use_remote_estimate	BOOL	Indicates whether to use an external cluster for planning a query. Based on the flag, query costs are estimated and the number of executors on segments is calculated. If `use_remote_estimate = true`, a parallel cursor is created and the number of executors is determined according to the number of parallel cursor endpoints. Otherwise, the number of executors is taken from `num_segments`, and if this parameter is not filled — the current number of segments is used. For more information, see ADB to ADB Connector overview. Possible values: `true` `false`	false	No
num_segments	INT	The number of executors on segments that are used to process data received from the parallel cursor endpoints. If the number of local cluster segments is smaller than the number of endpoints, some local cluster executors will get more endpoints (which will cause processing skew). Positive integers >= `1` are allowed	—	No
fdw_startup_cost	DOUBLE	The cost estimate for obtaining the first tuple from the data source Positive double values are allowed	100.0	No
fdw_tuple_cost	DOUBLE	The cost estimate for obtaining one tuple from the data source Positive double values are allowed	0.01	No
fetch_size	INT	The number of rows in the data batch read by the connector. Positive integers >= `1` are allowed	100	No
updatable	BOOL	Indicates the ability to change tables on the remote ADB cluster side via the `INSERT` command. Possible values: `true` `false`	true	No

Validation rules for the host and port options

- The maximum length of the `host` value is 255 characters.
- You can use in the `host` value digits `0-9`, ASCII characters `a-zA-Z`, hyphens `-`, underscores `_`, and dots `.`.
- The maximum length of the `port` value is 5 characters.
- Only digits `0-9` are allowed in the `port` value.

User mapping

To create a user mapping, use the `CREATE USER MAPPING` command. The basic command syntax is listed below:

```
CREATE USER MAPPING FOR { <username> | USER | CURRENT_USER | PUBLIC }
    SERVER <server_name>
    [ OPTIONS ( <option> '<value>' [, ... ] ) ]
```

where:

- `<username>` – a user name in ADB. The following constants are allowed:
  - `USER` or `CURRENT_USER` — the current user who established the ADB connection.
  - `PUBLIC` — all present and future ADB users.
- `<server_name>` – a server name.
- `<option>` – user mapping options, which typically include a user name and a password to connect to an external data source. The options that are available for ADB to ADB Connector are listed in the User mapping options table.
- `<value>` – option values.

NOTE

- To create a user mapping, you should be the owner of the corresponding server.
- The full description of the `CREATE USER MAPPING` command syntax is available in the Greenplum documentation.
- To edit a user mapping definition, use the ALTER USER MAPPING command. To delete a user mapping, use DROP USER MAPPING.

User mapping options

Name	Type	Description	Default	Required
user	TEXT	A user name in the remote ADB database	—	Yes
password	TEXT	A user password in the remote ADB database	—	Yes

Provide access via pg_hba.conf

In addition to a user mapping creation, you should provide an access of the selected user to the remote ADB database from the local cluster. Add the following record to the *pg_hba.conf* file on the remote ADB cluster side:

```
host    <database_name>  <remote_user>     <local_coordinator_address>     password
```

where:

- `<database_name>` – a name of the target database in the remote ADB cluster. The `all` value means all databases.
- `<remote_user>` – a user name in the remote ADB database (see the `user` option above).
- `<local_coordinator_address>` – an IP address of the coordinator host in the local ADB cluster (from which you plan to send queries). Use a subnet number. For example, `10.92.17.84/32`.

You can modify the *pg_hba.conf* file via the ADCM web interface. To do this, fill in the ***Custom pg_hba section*** parameter on the ***Configuration*** tab of the ***ADB*** service in the remote ADB cluster. To apply changes, click ***Save*** and run the service action ***Reconfigure***.

Foreign table

To create a foreign table, use the `CREATE FOREIGN TABLE` command. The basic command syntax is listed below:

```
CREATE FOREIGN TABLE [ IF NOT EXISTS ] <table_name> ( [
    <column_name> <data_type> [ COLLATE <collation> ] [ <column_constraint> [ ... ] ]
      [, ... ]
] )
    SERVER <server_name>
    [ OPTIONS ( <option> '<value>' [, ... ] ) ]
```

where:

- `<table_name>` – a foreign table name in ADB.
- `<column_name>` – a column name.
- `<data_type>` – a column data type.
- `<collation>` – a column collation.
- `<column_constraint>` – a constraint defined at the column level. The name `<constraint_name>` is given optionally. The syntax:

```
[ CONSTRAINT <constraint_name> ]
{ NOT NULL |
  NULL |
  DEFAULT <default_expr> }
```

Possible constraints:

- `NOT NULL` – specifies that the column is not allowed to contain null values.
- `NULL` – specifies that the column is allowed to contain null values. It is the default behavior (unless `NOT NULL` is specified).
- `DEFAULT` – sets the default column value equal to `<default_expr>`.

- `<server_name>` – a server name.
- `<option>` – foreign table options. For ADB to ADB Connector, all options defined at the server level (except `host` `port` `num_segments`) can be overwritten at the foreign table level (partially or fully). When you specify an option for a server and a foreign table at the same time, the table level takes precedence. Additionally, at the foreign table level, three more options are available (see Foreign table options below).
- `<value>` – option values.

NOTE

- To create a foreign table, you need the `USAGE` privilege on the corresponding server and on all column data types that are used in the table definition. The user who creates the foreign table becomes its owner.
- The full description of the `CREATE FOREIGN TABLE` command syntax is available in the Greenplum documentation.
- To edit a foreign table definition, use the ALTER FOREIGN TABLE command. To drop a foreign table, use DROP FOREIGN TABLE.

Foreign table options

Name	Type	Description	Default	Required
schema_name	TEXT	A schema name that is used to access a table on the remote ADB cluster side. If the parameter is undefined, a schema of the `table_name` table is used.	—	No
table_name	TEXT	A target table name on the remote ADB cluster side	—	Yes
column_name	TEXT	A column name of the target table `table_name`	—	No

ADB to ADB Connector usage examples

Select data

Insert data

This article describes how to transfer data between two ADB clusters via ADB to ADB Connector. The following prerequisites are met:

- The local ADB cluster is installed according to the Online installation guide.
- The remote ADB cluster is installed according to the Online installation guide. The coordinator host is called `bds-mdw-ext.ru-central1.internal`.
- The `adb` database exists in both clusters.
- The `adb_to_adb` user with password `123` exists in the remote cluster.
- The `adb_to_adb` user can access the remote `adb` database from the local cluster. For this purpose, change the *pg_hba.conf* file according to the ADB to ADB connector configuration article:

```
host    all  adb_to_adb       10.92.17.84/32     password
```

  where `10.92.17.84/32` is IP address of the coordinator host in the local ADB cluster (with a subnet number).

- ADB to ADB Connector is installed in the local and remote clusters according to the ADB to ADB connector installation guide.

Select data

To check that the remote ADB cluster data can be read from the local cluster, follow the steps:

1. Connect to the `adb` database in the remote ADB cluster under the `gpadmin` user (for example, via `psql`). Create the `author` table:

```
CREATE TABLE author(id INT NOT NULL, name TEXT NOT NULL)
WITH (appendoptimized=true)
DISTRIBUTED BY(id);
```

2. Insert some data into the `author` table (on the remote cluster side):

```
INSERT INTO author(id, name) VALUES
(1,'Virginia Woolf'),
(2,'J.R.R. Tolkien'),
(3,'Harper Lee'),
(4,'J.D. Salinger'),
(5,'George Orwell'),
(6,'John Steinbeck'),
(7,'Margaret Mitchell'),
(8,'Alan Moore'),
(9,'Jack Kerouac'),
(10,'Ernest Hemingway');
```

3. Grant necessary permissions on the new table `author` to the `adb_to_adb` user (on the remote cluster side):

```
GRANT SELECT, INSERT ON public.author TO adb_to_adb;
```

4. Connect to the `adb` database in the local ADB cluster under the `gpadmin` user (for example, via `psql`). Create the following objects in the given order.

   - The `test_server` server:

   ```
   CREATE SERVER test_server
   FOREIGN DATA WRAPPER adb_fdw
   OPTIONS (
     host 'bds-mdw-ext.ru-central1.internal',
     port '5432',
     dbname 'adb',
     use_remote_estimate 'true');
   ```

   - The user mapping for the `gpadmin` user:

   ```
   CREATE USER MAPPING FOR gpadmin
   SERVER test_server
   OPTIONS (user 'adb_to_adb', password '123');
   ```

   - The `test_table` foreign table:

   ```
   CREATE FOREIGN TABLE test_table (id INT, name TEXT)
   SERVER test_server
   OPTIONS (table_name 'author');
   ```

5. Select data from the `test_table`. Ensure that the data added on the remote cluster side is available in the local cluster:

```
SELECT * FROM test_table ORDER BY id;
```

   Result:

```
 id |       name
----+-------------------
  1 | Virginia Woolf
  2 | J.R.R. Tolkien
  3 | Harper Lee
  4 | J.D. Salinger
  5 | George Orwell
  6 | John Steinbeck
  7 | Margaret Mitchell
  8 | Alan Moore
  9 | Jack Kerouac
 10 | Ernest Hemingway
(10 rows)
```

Insert data

To check that you can add data to the remote ADB database from the local cluster, follow the steps:

1. Perform steps 1—4 that are listed above (if you have not passed them yet).
2. Connect to the `adb` database in the local ADB cluster under the `gpadmin` user (for example, via `psql`). Add some data to the `test_table` foreign table:

```
INSERT INTO test_table(id, name) VALUES
(11, 'Fyodor Dostoevsky'),
(12, 'Alexander Pushkin'),
(13, 'Mikhail Bulgakov');
```

3. Connect to the `adb` database in the remote ADB cluster under the `gpadmin` user (for example, via `psql`). Check the presence of new tuples in the `author` table:

```
SELECT * FROM author ORDER BY id;
```

   The result contains new data received from the source ADB cluster:

```
 id |       name
----+-------------------
  1 | Virginia Woolf
  2 | J.R.R. Tolkien
  3 | Harper Lee
  4 | J.D. Salinger
  5 | George Orwell
  6 | John Steinbeck
  7 | Margaret Mitchell
  8 | Alan Moore
  9 | Jack Kerouac
 10 | Ernest Hemingway
 11 | Fyodor Dostoevsky
 12 | Alexander Pushkin
 13 | Mikhail Bulgakov
(13 rows)
```

The parameters described here refer to the configuration file (default name: config.ini). To open the configuration file, click the Settings button in the Control panel.

CSS

Control of appearance (known under the old name CSS) via the Control panel

CSS control

Parameter	Description	Default value
Name of default CSS file	Name of the default CSS file in the /css/ folder.	ezs3
Name of CSS file for mobile devices	Name of the CSS file in the /css/ folder for mobile devices.	ezs3
Type of zooming	Type of zooming in the browser: **classic** - Default zooming in the browser, **modern** - Zooming in the browser with the help of the CSS property zoom, **none** - Zooming in the browser is disabled.	classic
Width of the browser window	Width of the browser window in pixels. If the value is set to **0**, the width of the browser window is not limited.	0
Width of the browser window for mobile devices	Width of the browser window in pixels for mobile devices. If the value is set to **0**, the width of the browser window is not limited.	0
Width of the browser window for tablets	Width of the browser window in pixels for tablets. If the value is set to **0**, the width of the browser window is not limited.	0
Allow the user to change the CSS	Allow the user to change the CSS in the Control panel.	**yes**
Allow the user to change the CSS for mobile devices	Allow the user to change the CSS for mobile devices in the Control panel.	**yes**
Allow the user to change the CSS for tablets	Allow the user to change the CSS for tablets in the Control panel.	**yes**
Allow the user to change the CSS for desktops	Allow the user to change the CSS for desktops in the Control panel.	**yes**
Disable the CSS	Disable the CSS in the Control panel.	**no**
Disable the CSS for mobile devices	Disable the CSS for mobile devices in the Control panel.	**no**
Disable the CSS for tablets	Disable the CSS for tablets in the Control panel.	**no**
Disable the CSS for desktops	Disable the CSS for desktops in the Control panel.	**no**
Hide the CSS	Hide the CSS in the Control panel.	**no**
Hide the CSS for mobile devices	Hide the CSS for mobile devices in the Control panel.	**no**
Hide the CSS for tablets	Hide the CSS for tablets in the Control panel.	**no**
Hide the CSS for desktops	Hide the CSS for desktops in the Control panel.	**no**
Name of the CSS file in the Control panel	Name of the CSS file in the Control panel.	Control
Name of the CSS file in the Control panel for mobile devices	Name of the CSS file in the Control panel for mobile devices.	Control
Name of the CSS file in the Control panel for tablets	Name of the CSS file in the Control panel for tablets.	Control
Name of the CSS file in the Control panel for desktops	Name of the CSS file in the Control panel for desktops.	Control

HTML

The parameters here refer to the **ezs3.ini** file.

Parameter	Description	Default value
Name of the default HTML file	Name of the default HTML file in the /html/ folder.	index
Name of the HTML file for mobile devices	Name of the HTML file in the /html/ folder for mobile devices.	index
Name of the HTML file for tablets	Name of the HTML file in the /html/ folder for tablets.	index
Name of the HTML file for desktops	Name of the HTML file in the /html/ folder for desktops.	index
Name of the HTML file in the Control panel	Name of the HTML file in the Control panel.	Control
Name of the HTML file in the Control panel for mobile devices	Name of the HTML file in the Control panel for mobile devices.	Control
Name of the HTML file in the Control panel for tablets	Name of the HTML file in the Control panel for tablets.	Control
Name of the HTML file in the Control panel for desktops	Name of the HTML file in the Control panel for desktops.	Control

Control

Parameter	Description	Default value
Name of the default HTML file in the Control panel	Name of the default HTML file in the Control panel.	**ezs3.ini**
Name of the password file in the Control panel	Name of the password file in the Control panel.	

CSP

Parameter	Description	Default value
Use CSP	Use CSP.	**no**
CSP value	Value of the CSP.	default-src 'self' data:;
Allow connections	Allow connections to the CSP source in the.	
Allow font loading	Allow font loading in the CSP.	
Allow image loading	Allow image loading in the CSP.	
Allow media files	Allow media files in the CSP.	
Allow object loading	Allow object loading in the CSP.	
Allow script loading	Allow script loading in the CSP.	
Allow style loading	Allow style loading in the CSP.	
Allow worker loading	Allow worker loading in the CSP.	
Allow manifest loading	Allow manifest loading in the CSP.	
Allow prefetching	Allow prefetching in the CSP.	
Allow frame loading	Allow frame loading in the CSP.	
Allow form submission	Allow form submission in the CSP.	
Allow base URI	Allow base URI in the CSP.	
Allow navigation	Allow navigation in the CSP.	
Allow frame ancestors	Allow frame ancestors in the CSP.	
Allow plugin types	Allow plugin types in the CSP.	
Allow sandbox	Allow sandbox in the CSP.	
Allow report URI	Allow report URI in the CSP.	
Allow trusted types	Allow trusted types in the CSP.	
Allow require trusted types for	Allow require trusted types for in the CSP.	
Allow upgrade insecure requests	Allow upgrade insecure requests in the CSP.	
Allow block all mixed content	Allow block all mixed content in the CSP.	

Files

Parameter	Description	Default value
Starting file directory	Location path of the key file.	

ACME Control

Parameter	Description	Default value
Activate ACME Control in the Control panel	Activate ACME Control in the Control panel.	**no**
Activate ACME Control in the Control panel for mobile devices	Activate ACME Control in the Control panel for mobile devices.	**no**
Activate ACME Control in the Control panel for tablets	Activate ACME Control in the Control panel for tablets.	**no**
Activate ACME Control in the Control panel for desktops	Activate ACME Control in the Control panel for desktops.	**no**

Installation parameters

Parameter	Description	Default value
Use	Use.	**no**
Use certificate	Use certificate.	**no**
Use private key	Use private key.	**no**

Supported extensions

Dana Barysheva

To Table of Contents

Extensions are special modules that provide additional database functionality by bundling several SQL objects into a package to use them as a single unit. Extensions provide various functions, operators, data types, etc.

Below is a full list of extensions that are available in Arenadata DB.

Extension name	Version	Description	Enterprise only	Deployment type
adb_fdw	1.0	Implements a foreign data wrapper that provides two-way interaction between ADB clusters	+	ADB to ADB Connector
address_standardizer	3.3.2	Rule-based address standardizer that is used to parse an address into constituent elements	-	ADB service → Install PostGIS action
address_standardizer_data_us	3.3.2	Provides sample rule tables for US address data	-	ADB service → Install PostGIS action
arenadata_toolkit	1.0	Used for manipulating the arenadata_toolkit schema and its objects	-	ADB service
btree_gin	1.3	Provides support for indexing common data types in GIN	-	`CREATE EXTENSION btree_gin;`
citext	1.6	Implements a data type for case-insensitive character strings	-	`CREATE EXTENSION citext;`
dblink	1.2	Supports connections to other PostgreSQL databases from within a database session	-	ADB service
diskquota	2.3	Allows you to limit the amount of disk space used by schemas, roles, or tablespaces in a database	-	ADB service → Install diskquota action
file_fdw	1.0	Implements the foreign data wrapper for server-side flat files	-	`CREATE EXTENSION file_fdw;`
fuzzystrmatch	1.1	Provides functions to determine similarities and distance (e.g. Levenshtein) between strings based on various algorithms	-	`CREATE EXTENSION fuzzystrmatch;`
gp_distribution_policy	1.0	Allows you to check distribution policies in a cluster	-	`CREATE EXTENSION gp_distribution_policy;`
gp_exttable_fdw	1.0	Converts an external table to a foreign table	-	`CREATE EXTENSION gp_exttable_fdw;`
gp_internal_tools	1.0.0	Provides different internal tools for Greengage DB	-	`CREATE EXTENSION gp_internal_tools;`
gp_legacy_string_agg	1.0.0	Implements the legacy single-argument function `string_agg` in Greengage DB	-	`CREATE EXTENSION gp_legacy_string_agg;`
gp_sparse_vector	1.0.1	Implements SParse vectors in Greengage DB	-	`CREATE EXTENSION gp_sparse_vector;`
gp_toolkit	1.8	Provides information from system catalogs, cluster logs, and environment status	-	`CREATE EXTENSION gp_toolkit;`
gpadcc	0.8	Used by the ADB Control service	+	ADB Control service
hstore	1.6	Implements a data type for storing sets of key/value pairs within a single data field	-	`CREATE EXTENSION hstore;`
isn	1.2	Provides support for international product numbering standards	-	`CREATE EXTENSION isn;`
kadb_fdw	0.16	Implements a foreign data wrapper that provides interaction between Kafka and ADB	+	Kafka to ADB Connector
ltree	1.1	Implements a data type for hierarchical tree-like structures	-	`CREATE EXTENSION ltree;`
madlib	2.1.0	A scalable in-database analytics library	-	ADB service → Install MADlib action
orafce	4.9	Implements SQL functions and operators that emulate a subset of functions and packages from the Oracle database	-	`CREATE EXTENSION orafce;`
pageinspect	1.9	Used to inspect the contents of database pages at a low level	-	`CREATE EXTENSION pageinspect;`
pg_buffercache	1.4.1	Provides real-time access to the contents of the shared buffer cache	-	`CREATE EXTENSION pg_buffercache;`
pg_hint_plan	1.3.9	Allows controlling the query planner's execution plan by using hints embedded in SQL comments	-	`CREATE EXTENSION pg_hint_plan;`

pg_stat_statements	1.7	Allows tracking planning and execution statistics of all SQL statements executed by a server	-	In the `adb` database, run:
				`CREATE EXTENSION pg_stat_statements;`
				On the coordinator host, add `pg_stat_statements` to the `shared_preload_libraries` server configuration parameter, and then restart the DBMS:
				`$ gpstop -r`

pg_trgm	1.4	Provides text similarity measurement and index searching based on trigram matching	-	`CREATE EXTENSION pg_trgm;`
pgcrypto	1.3	Implements cryptographic functions (encryption/decryption)	-	`CREATE EXTENSION pgcrypto;`
plperl	1.0	Provides support for PL/Perl procedural language	-	`CREATE EXTENSION plperl;`
plperlu	1.0	Provides support for PL/PerlU untrusted procedural language	-	`CREATE EXTENSION plperlu;`
plpgsql	1.0	Provides support for PL/pgSQL procedural language	-	ADB service
plpython3u	1.0	Provides support for PL/Python3U untrusted procedural language	-	`CREATE EXTENSION plpython3u;`
plpythonu	1.0	Provides support for PL/PythonU untrusted procedural language	-	`CREATE EXTENSION plpythonu;`
postgis	3.3.2	Provides PostGIS geometry, geography, and raster spatial types and functions	-	ADB service → Install PostGIS action
postgis_raster	3.3.2	Provides support for raster data	-	ADB service → Install PostGIS action
postgis_sfcgal	3.3.2	Implements PostGIS SFCGAL functions	-	ADB service → Install PostGIS action
postgis_tiger_geocoder	3.3.2	Provides the PostGIS TIGER geocoder and reverse geocoder	-	ADB service → Install PostGIS action
postgres_fdw	1.0	Implements a foreign data wrapper for remote PostgreSQL servers	-	`CREATE EXTENSION postgres_fdw;`
pxf	2.1	Allows you to access unmanaged data	-	PXF service → ***install*** action
pxf_fdw	1.0	Implements a foreign data wrapper for PXF	-	PXF service → ***install*** action
sslinfo	1.2	Provides information about SSL certificates	-	`CREATE EXTENSION sslinfo;`
tablefunc	1.1	Provides functions that return tables (e.g. `crosstab`)	+	`CREATE EXTENSION tablefunc;`
tkh_fdw	1.0	Implements a foreign data wrapper that provides two-way interaction between ADB and ClickHouse	+	ADB ClickHouse Connector
uuid-ossp	1.1	Provides functions to generate universally unique identifiers (UUIDs)	-	`CREATE EXTENSION "uuid-ossp";`

SQL commands not supported in ADB

Daria Barysheva

To Table of Contents

Though Arenadata DB is based on PostgreSQL, some SQL commands and operators are not supported in ADB. This is due to the features of distributed databases. Below is a list of SQL commands that are currently missing in ADB.

NOTE

For more information on all SQL commands (including supported ones), see the Greenplum documentation.

SQL command
ALTER SYSTEM
ALTER TRIGGER
ALTER PUBLICATION
ALTER SUBSCRIPTION
COMMIT PREPARED
CREATE CONSTRAINT TRIGGER
CREATE PUBLICATION
CREATE SUBSCRIPTION
CREATE TRIGGER
DROP OWNED
DROP PUBLICATION
DROP SUBSCRIPTION
DROP TRIGGER

ADB 7 releases

Daria Barysheva

Contents

To Table of Contents

7.4.1
7.4.0
7.2.0

7.4.1

7.4.1.1

Date: 23.12.2025

New features

Implemented ADBM 2.8.1

Implemented ADB Control 4.15.1

Bug fixes

The ***Move Host Segment***, ***Expand***, and ***Init Standby Master*** cluster actions reboot only new hosts now

Fixed an issue with switching to the standby coordinator when using the ***force activation*** mode

Fixed an issue where the ADB to ADB connector could hang during parallel retrieve cursor closure

Fixed an issue where reading from a foreign table within a transaction could fail

Fixed an issue with dispatching `DROP` commands to segments when the object is missing on the coordinator

Fixed an issue where temporary files could remain in the system if a query with a materialized CTE was interrupted by an error

7.4.0

7.4.0.1

Date: 28.11.2025

New features

The release includes the following components: ADBM, ADB Control, and connectors (ADB ClickHouse, ADB to Kafka and Kafka to ADB, ADB to ADB). Offline installation is supported

Migrated ADB to Greengage DB

DBeaver has been adapted to work with Greengage DB. Use version 25.2.3 or later

Added support for Linux cgroup v2, allowing you to limit disk throughput

Implemented orphaned file cleanup

Added the ability to define a distribution key for `Redistribute Motion` when using foreign tables

Added support for LDAP authentication

Added support for LLVM 18

Implemented TLS options for PXF external tables and foreign data wrappers (FDWs)

Implemented ADBM 2.8.0

Implemented ADB Control 4.15.0

Improvements

Refactored `arenadata_toolkit`. The extension has been aligned with the latest Greengage DB architecture, and several components have been reorganized with part of the functionality moved into the `gp_toolkit` extension

Implemented a precheck to ensure a standby coordinator cannot be added when mirroring is not enabled

Refactored OS parameter handling and added a precheck to validate required system settings

Added support for selecting `group` or `spread` mirroring

Added SSL support for connections between `pxf_fdw` and the PXF service

Enabled support for the `DEXTRA_DYNAMIC_MEMORY_DEBUG` macro

Disallowed inlining of CTEs containing DML operations

Raised a planner error for `SELECT INTO` queries containing modifying CTEs

Enabled JSON output for `EXPLAIN ANALYZE` statistics

Prevented WAL removal during recovery when `archive_mode=always`

Added an explicit error when specifying `ENCODING` for foreign-table columns

Added `EXPLAIN ANALYZE` statistics for queries with DML inside CTEs

Added a default transformation flag for `gpfdist` applied automatically when a table has no transformation level defined

Ensured `gpcloud` compatibility with OpenSSL 1.1.1

Added a check to ensure the previous expand action completed successfully before starting the next one

Bug fixes

Fixed an issue where temporary schemas were not cleaned up after segment failures

Fixed an issue where `pg_dump` generated an invalid `DROP EXTERNAL TABLE` statement that prevented proper restoration

Fixed `gplogfilter` so that time-range filters correctly skip irrelevant files

Fixed an issue where disk space was not promptly reclaimed after dropping temporary tables

Fixed an issue where GUCs on segments were not updated when running `gpstop -u`

Fixed a crash when running `EXPLAIN (ANALYZE, FORMAT JSON)` for `gp_toolkit.gp_table_size_skew_coefficients()`

Fixed an issue where inserts failed if `default_tablespace` pointed to a non-existing tablespace

Fixed incorrect calculation of space used by spill files when multiple processes run in the same session

Fixed an issue where `VACUUM` could corrupt the bitmap index of an AO table on mirror segments

Fixed an issue where LDAP connections ignored `hostssl` and did not use SSL for the specified users

Fixed an issue preventing the use of wildcard characters in interconnect addresses

Fixed an issue in the `tablefunc` extension that prevented using DML queries

Fixed incorrect memory allocation when generating statistics for hash join queries

Misc

MADlib is now delivered as an extension

7.2.0

7.2.0.1

Date: 19.09.2024

Improvements

The output of the `EXPLAIN` command in JSON mode has been fixed to provide more accurate query execution details

GPDB compilation will now fail if compiler warnings occur, improving build quality

Implemented error reporting for invalid operations involving CTEs in the `SELECT INTO` statements

Interruption of LDAP requests by signals will no longer be treated as an authentication error, enhancing stability

Official support for Ubuntu 22.04 on x86-64 platform has been added

The query analysis logic has been moved to the PostgreSQL core, improving performance and integration

Simplified the `dbid` detection logic to improve the reliability of the `pg_rewind` command

Optimized the row counting mechanism in replicated tables for DML operations

Updated the data distribution logic to ensure proper handling of combined hash specifications

Python 3.11 is now supported, enhancing container operations

Updated the CTE processing mechanism to always materialize data if it is used outside of `SELECT`

Incorporated the latest `timezone` data updates for more accurate time zone management

Updated JIT support to enhance query performance in GPDB

Added documentation for running JIT tests and updated LLVM support to the latest versions

Fixed Dockerfile for proper execution of the GPDB 7 test suite and added support for Java 11

Bug fixes

Resolved resource leaks during errors while executing the `COPY TO/FROM PROGRAM` commands

Addressed compilation warnings to improve compatibility with modern compilers

Corrected an issue that occurred when switching the access method to columnar for tables

Resolved an issue that caused a segmentation fault when calculating compression ratios for AO tables

Resolved an issue where temporary schemas were not properly cleaned up after segment failures

Addressed errors related to incorrect row access during the analysis of AOCO tables

The `gpstop -u` command logic has been updated to ensure that GUC parameters are properly applied on segments

ADB 7 known issues

Anton Vasilev

To Table of Contents

Issue	From	Fixed	Workaround

Ansible task hangs indefinitely on a specific host during package installation or APT cache update	7.4.0	—	Solution:
			1. On the target host, identify the processes locked by APT:
			`$ ps aux | grep apt`
			2. Terminate found processes:
			`$ kill <PID>`
			Once the hanging processes are terminated, the task will retry automatically. Make sure to terminate the hanging processes on all affected hosts — in this case, the ADCM action will resume its operation, and you can restart it in the ADCM UI.
			As a prevention measure, disable and stop `apt-daily-upgrade.timer`, `apt-daily.timer`, and `apt-daily.service` to prevent background auto-updates from locking APT:
			`$ sudo systemctl disable apt-daily-upgrade.timer apt-daily.timer apt-daily.service`
			`$ sudo systemctl stop apt-daily-upgrade.timer apt-daily.timer apt-daily.service`

ADB 6 known issues

A Time Machine™ for ADB

To Table of Contents

Issue	From	Fixed	Workaround
`gp_toolkit.gp_segconfigs` can sum up the `numsegments` of every segment, unnecessarily	–	–	Do not install or update `pivotalresql` supplied by RED OS repositories. The package is installed on all systems during ADB6 installation and upgrades

In case of requests that have a sink operator on the coordinator, split files remains in `gp_toolkit.gp_workfile_entries` and `gp_toolkit.gp_workfile_usage_per_query` might be duplicated (with `segid=-1`) and overstate the amount of data	–	–	Use `SELECT DISTINCT ON (segid, sess_id, command_cnt, prefix)` to avoid duplicates during ADB6 installation and upgrades
			• Get information about all spill files:
			`SELECT DISTINCT ON (segid, sess_id, command_cnt, prefix) * FROM gp_toolkit.gp_workfile_entries ORDER BY segid, sess_id, command_cnt, prefix, size;`
			• Get total space usage for different sessions and segments:
			`SELECT sess_id, segid, SUM(size) AS total_size, SUM(numfiles) AS total_files FROM (SELECT DISTINCT ON (segid, sess_id, command_cnt, prefix) segid, size, numfiles FROM gp_toolkit.gp_workfile_entries) t GROUP BY segid, sess_id ORDER BY segid, sess_id;`

There is an error in the description of the `CREATE` option of the `ALTER RESOURCE GROUP` command in the manual	–	–	Use the correct description provided in the first table column
Actually, the `segment_config` value contains the `-w` option, even when `wal_keep_segments` is `0`	6.27.1.0?	–	To ensure the correct handling of the `filespace with (one)` type, PXF does not always perform push-down
Some `SIGHUP` parameters (e.g. `shutdown_timeout`) may be changed only after restart of the `gpstart` console utility under the `gpadmin` user account in Linux	6.29.2.52	–	When switching to `gpadmin`, do not use `sudo - su gpadmin` – use `sudo -i` instead: `sudo su - gpadmin`
If you made a backup via `gpbackup` to ADB cluster of a version preceding 6.25.3.12.61 and try to restore a database backup to ADB 6.25.3.12.61 via `gprestore`, you can get the following error:	6.25.3.12.61	–	Drop `PROCEDURAL LANGUAGE plpythonu` in a target database before running `gprestore`
`[CRITICAL]:-ERROR: language "plpythonu" already exists (SQLSTATE 42710)`			
If you made a backup via `gpbackup` to ADB cluster of a version preceding 6.25.3.12.61 and try to restore a database backup to ADB 6.25.3.12.61 via `gprestore`, you can get the following error:	6.25.3.12.61	–	1. Run `gprestore` with the `--truncate-untar` and `--on-error-continue` options 2. Check that there are not any critical errors in error log (if errors are present, ask the necessary restorations manually) 3. Run `gprestore` with the `--incremental` option to restore data
`[CRITICAL]:-ERROR: function public.dblink_connect_u_auth(text) does not exist (SQLSTATE 42883)`			
If you made a backup via `gpbackup` to ADB cluster of a version preceding 6.25.3.12.61 and try to restore a database backup to ADB 6.25.3.12.61 via `gprestore`, you can get the following errors:	6.25.3.12.61	–	Update the extension packages: `gpCC` and `gpcf_fdw` in each database that uses these extensions and then update the extensions To restore a backup, you only need to update the packages
`[CRITICAL]:-ERROR: Incompatible library "/usr/lib/gpdb/lib/postgresql/gpdb_spd_version-1.so": version mismatch (SQLSTATE XX000)`			
or			
`[CRITICAL]:-ERROR: required extension "gpcf_fdw" is not installed (SQLSTATE XX000)`			

The `SELECT` query in `gpmaintain_toolkit.__db_files_current` has errors	6.24.1.45	–	The `psql` command to the database where you gather statistics (e.g. `adb`), under a superuser:
			`$ psql adb -U <superuser>`
			2. Run the following command to alter the function:
			`ALTER FUNCTION gpmaintain_toolkit.adb_get_relfilenodes(tablespace_oid OID) VOLATILE;`

`psql:/tmp/tmpAtdmin:1: ERROR: illegal value of multixact_member_buffers configuration (file): (null)0: allocation of 18014398509481984 bytes failed with Cannot allocate memory DETAIL: Likely caused by bad %-jobs, try setting enable_maxthreads to off`	6.24.3.48	–	1. Backup logs from the pg_log directory 2. Clear or compress log files. 3. Restart ADB

`[CRITICAL]:-table bonuses has no column named segment_count`	6.24.3.48
	6.25.3.12.61
		–	Use one of the following options (each one comes with certain limitations):
			• **Option 1**: Use the `SIGHUP` `timestamp` and `integer` `history` gpconfig parameters together for incremental backups. This option is not helpful when a plugin is used.
			• **Option 2**: Drop the old history database file (backup_history.db) after upgrade to `gpbackup` of version 1.26.1 or higher
			3. Run `$MASTER_DATA_DIR/gpmaintain_toolkit/gpbackup_history_db.sh` to delete:
			You have to proceed with full backups to restore data from incremental backups and promote the backup stage work
			• **Option 3**: Alter the `history` table schema in the `backup_history.db` SQLite database:
			`$ sqlite3 $MASTER_DATA_DIR/gpseg-1/gpbackup_history.db`
			`ALTER TABLE backups ADD COLUMN segment_count INT; pragma table_info('backups');`
			You have to provide a valid number of segments if the rescue restore operation is requested

The ADB bundle update action can fail with the following error: `failed: Unable to connect to database template1 ALTER/CREATE database template1 failed`			
After updating ADB to version 6.24.3.48.61 or higher, the `gpbackup` command can return an error: `gpbackup: ignoring`	6.24.3.48 6.25.3.12.61	–	Use one of the following options (each one comes with certain limitations): • **Option 1**: Use the `SIGHUP` `timestamp` and `integer` `history` gpconfig parameters together for incremental backups. This option is not helpful when a plugin is used. • **Option 2**: Drop the old history database file (backup_history.db) after upgrade to `gpbackup` of version 1.26.1 or higher 3. Run `$MASTER_DATA_DIR/gpseg-1/gpbackup_history.db` to delete:
`[CRITICAL]:-table bonuses has no column named segment_count`			
The error occurs due to the fact that in `gpbackup` of version 1.26.1 the `segment_count` field was added to the `backups` table in the previous ADB 6 database `backup_history.db`. This fix or rollback is used to: • Find a previous completed backup with the same options to create an incremental backup (if the `--prev-timestamp` option is not specified). • During the restore process, to exclude the `segment_count` field from the table that was used to create the specified backup. Another side effect of the column absence is the incorrect value for a number of segments in the report of the backup made. It leads to an error during a rescue restore operation			
When data is selected from ClickHouse via a PXF connector, the error `Illegal type Int32 of column for filter is not a number in use with such name.`	6.24.3.47	–	Do not use a password for the `default` user
`DB::Exception: Default authentication failed: Password is incorrect or there is no user with such name.`			
Due to technical limitations in the ADB VMtrack plugin, the `history_keeper` plugin option is automatically set to `off` when the `vmtrack_enable` option is set to `on`	6.23.0.38	–	Do not use the `on-error-continue` option during data restore
Expanding a cluster may fail if fully qualified domain names (FQDNs) are used in the cluster hosts and the `hostname -f` command returns a non-zero exit code	6.16.1.20	–	Unset the `Check` env flag during the cluster expansion process if FQDNs are used in the cluster
When resource management based on resource groups is active, the memory allocated to a segment can be exceeded by active primary segments. Assigning of memory to primary segments happens when the segment starts the primary role. Memory allocated to a mirror segment is calculated starting a cluster (with `gpstart`), and does not change, even if the segment switches to the primary role. Therefore, in some scenarios, the memory allocated to a segment may result in a segment fault when executing queries. See `gp_resource_group_memory_limit` setting permits.	6.12.1.11	–	Restart your cluster to recalculate memory allocation in cases of increased number of primary segments or hosts (e.g. after failover)
For more information, refer to the VMware documentation			
There is an error in the `COPY` command description of the `FILL_MISSING_FIELDS` option	6.12.1.11	–	Use the correct option provided in the first table column
ADB monitoring may raise an issue for exceeding the limit of RAM to be used with the following error: `nanhg:Bad(timeout) 4778(dirt), 4096 not found in second column of smaps?(1, setpat between 12444 e 2ed 0`	6.12.1.11	–	Run `vm.hanmond.collectors.SmartCollector.conf` parameter `scanfast = false`
`diskguards` may have table-statistics collection issues when the disk space is tested. The error is mostly due to locks `diskguards` calculates table sizes and stores that information as the `diskguards.table_size` view. Calculations are performed by the `diskguards.table_sizes()` function. By default, if you restart the ADB cluster or the `diskguards` service, the `diskguards` will lose all changes that have occurred since the last data save to the `diskguards.table_sizes` table. For example, you create a new table, insert the tests, rework the cluster, and `diskguards` will not know about such a change. Because the `diskguards.table_sizes` does not contain information about the new table, `diskguards` will not update data. It can be useful to manually run the `diskguards.table_sizes()` function (`diskguards.table_sizes_save`) to save changes. Such an action for large clusters can take a significant amount of time	6.12.1.11	–	Run `diskguards.table_sizes_save()` function in the background (`diskguards.table_sizes_save(true)`) to not connect. The right one is `diskguards.table_sizes_save(false)` `diskguards.table_sizes_save()` may cause issues with receiving composition statistics. Some data are updated correctly after resume
The formula for specifying the maximum number of table segments from the `gpmaintain.conf` documentation is not correct. The right one is: `diskquota.max_table_segments = vacuum_number_of_tables * (1+number_of_segments) and 200) * 1.5 + 100`	6.12.1.11	–	Use the correct formula provided in the first table column
When running `gpexpand` to add new segments to a cluster, the error `ERROR: Segment count in gp_segment_configuration (2) is not equal to value in pg_database.numsegments (3).` may occur	6.12.1.11	–	Recreate a table or, if possible, do not drop columns from a partitioned table if you are going to add new partitions after that
`SQL Error [22514]: ERROR: Trying to insert row into wrong partition`			
The issue reveals itself when some segments are not available for a partitioned table and the partitions are added via `ADD PARTITION` - `EXCHANGE PARTITION`			
In CentOS and Astra Linux, you can get the following error during the ADB 6 manual installation of `gpcc`:	6.27.1.56	6.27.1.56	Before ADB installation update, install Java 17 on cluster hosts and fill in the `JAVA_HOME` parameter on the hosts configuration page
ADB to ADB Connector installation fails due to the lack of extension files on segments	6.25.1.0? 6.25.2.52	–	Install the with-file package for all ADB segment nodes manually, e.g. install it on master via running `ipcrm` from master or run installation on each node
After updating ADB to version 6.23.2.44 with additional ADB Control Version from 6.23.1 to 6.23.1.45, you get inconsistency of agents and ADB Control versions in the UI	6.23.1.45	–	No workaround. Only upgrade to the **Fixed** version resolves the issue
`AssertionError: Action [Install] finished execution with unexpected result: {"status": "success", "ADB temp_client - Add ADB connection to ADS"}`			
In ADB 6 starting with 6.22.1.47, Mail6 uses a new port for its access Mail6 is unavailable after upgrading from previous versions of ADB 6	6.22.1.47	N/A	1. Backup the `mail2db` schema if necessary. 2. Drop the `mail2db` schema in the cascade mode 3. Run the **Install Mail2db** action for ADB service via ADCM 4. Restore schema objects from a backup

The shared library diskquota-2.0.so doesn't load
`shared_preload_libraries` during upgrade with the following log error or monitor: `FATAL: could not access file "$libdir/diskquota-2.0.so": No such file or directory`
	6.22.1.47	6.24.3.48	1. Ensure that the dry-run of the `3dd` utility works correctly:
			`$ sed 's/diskquota/diskquota-2.0/g' /data1/gpseg0/postgresql.conf`
			2. Run the `3dd` utility with the `-fi` parameter to apply changes:
			`$ sed -i 's/diskquota/diskquota-2.0/g' /data1/gpseg0/postgresql.conf`

During installation of the ansible module, you get the following error: `ERROR! Exception: library was not found: /usr/lib/libffi.so.7: cannot open shared object file: No such file or directory`	6.22.1.47	6.22.1.47	Copy the necessary library from /usr/lib/pu64/: `$ cp /usr/lib/pu64/libcrypto.so.1.0.0-fips /usr/lib/pu64/libcrypto.so.1.0.0-fips`

If you upgrade your cluster to 6.22.1.40 with installed ADCM, remember that during the process of `gpmaintain_toolkit.db_files_history` table migration into the upgrade process, rename the table before upgrade and return the source name after it	6.22.1.40	6.23.1.41	If you do not want to include the `gpmaintain_toolkit.db_files_history` table migration into the upgrade process, rename the table before upgrade and return the source name after it:
			1. Run the query:
			`ALTER TABLE gpmaintain_toolkit.db_files_history RENAME TO db_files_history_orig;`
			2. Run the **Upgrade** cluster action via ADCM and wait for a successful operation
			3. Run the query:
			`ALTER TABLE gpmaintain_toolkit.db_files_history_orig RENAME TO db_files_history;`

Kafka like of versions 0.7.5-0.7.12 (they were ported to 6.16.0-6.17.0 does not work correctly with Greenplum Database 6.x. The `copy_count > 0` and `copy_count = 0` keywords (`copy_count` is a count of messages) are not supported in the Greenplum Database 6.x version of ADB Kafka Connector `SIGFAULT`. The fix on the issue is described in the Kafka Release Notes	6.22.1.40	–	1. Uninstall ADCM before upgrading the ADB cluster to 6.22.1.40. 2. Run **Upgrade**. 3. Reinstall ADCM, after upgrade.
The `gpbackup` utility of versions 1.20.1-1.22.4 does not work correctly when foreign tables are present in a database. Backup of such tables is not supported `gpbackup --dbname adb --verbose` results in the following error:	6.16.1.20	6.16.2.21	Replace the current `gpbackup` with version 1.20.0 which is included in ADB 6.13.0.13

Attempt to upgrade a cluster with `gpcc_segment_configuration` and `gpcc_interval_storage_options` tables with `evenlydistributed` results in the following error:
`ERROR: "append-only tables do not support unique indexes"`
	6.12.1.11	6.25.1.40	1. Run
			`gp_default_storage_options='appendoptimized=false'`
			`gpcc_segment_configuration`
			2. Upgrade a cluster
			3. Revert
			`gp_default_storage_options='appendoptimized=true'`
			`gpcc_segment_configuration`

The `upgrade` command does not work correctly if `gp_default_storage_options` and `gp_default_storage_options` parameter for any database	6.12.1.11	6.24.3.48 6.25.3.12.61	Revert the `gp_default_storage_options` value to `appendoptimized=false` before the upgrade and set it to `true` after
`gpperfmon` was found with logs in `$MASTER_DATA_DIR/gpperfmon/logs` if it is not in use	6.12.1.11	6.23.0.40	1. Switch off the `gp_enable_gpperfmon` GUC: `$ gpconfig -c gp_enable_gpperfmon -v off`
			2. Purge the $MASTER_DATA_DIR/gpseg-1/gpperfmon/ directory

When you expand ADB by running the `Expand` cluster action, you can get errors if cluster hosts were expanded not with `gpexpand` utility but manually. In this case, the `hostname` and `address` columns in the `gp_segment_configuration` table are not updated correctly, which may cause errors during the `Expand` action	6.12.1.11	6.23.0.44	Before you expand an ADB cluster:
			1. Stop ADB, for example, via the following command:
			`$ gpstop -M fast`
			2. Start a master segment in the utility mode:
			`$ gpstart -m`
			3. Set the `allow_system_table_mods` GUC value to `true`:
			`$ psql adb`
			`SET allow_system_table_mods = 'true';`
			4. Fix `gp_segment_configuration` so that the `hostname` and `address` column values are the same:
			`UPDATE gp_segment_configuration SET hostname = address;`
			5. Stop and start ADB in a standard mode:
			`$ gpstop -m`
			`$ gpstart`

5.28.6

5.29.11

5.29.11.19

Date: 16.06.2023

New features

Synced with upstream Greenplum Database 5.29.11

Improvements

Upgraded `txh-connector` and `gpfxh` to the latest PXF 5 versions

Bug fixes

Fixed `FATAL: could not open relation` after the segments switchover

Fixed the `gpfxh` extension creation when extension scripts dropped anything

Fixed `ERROR: gp_relation_node has more entries than pg_aocsseg for relations`

5.29.8

5.29.8.18

Date: 13.10.2022

New features

Synced with upstream Greenplum Database 5.29.8

Improvements

Removed relcache in tablespaces located in non-default locations

5.29.6

5.29.6.18

Date: 15.06.2022

New features

Synced with upstream Greenplum Database 5.29.6

5.29.5

5.29.5.18

Date: 18.04.2022

New features

Synced with upstream Greenplum Database 5.29.5

5.29.4

5.29.4.18

Date: 03.03.2022

New features

Synced with upstream Greenplum Database 5.29.4

5.29.3

5.29.3.18

Date: 24.01.2022

New features

Synced with upstream Greenplum Database 5.29.3

Bug fixes

The `starve_case isolation2` test failed with ORCA

5.29.2

5.29.2.17

Date: 22.12.2021

New features

Synced with upstream Greenplum Database 5.29.2

5.29.1

5.29.1.17

Date: 26.11.2021

New features

Synced with upstream Greenplum Database 5.29.1

Updated `gpbackup` to 1.22.0_arenadata5

5.29.0

5.29.0.16

Date: 03.11.2021

New features

Synced with upstream Greenplum Database 5.29.0

5.28.14

5.28.14.16

Date: 30.08.2021

New features

Synced with upstream Greenplum Database 5.28.14

Updated `pgbouncer` to 1.16.0

Updated PXF to 5.16.3_arenadata2

Updated `gpbackup` to 1.21.0_arenadata3

Updated `gpbackup_s3_plugin` to 1.7.0_arenadata1

Bug fixes

Restricted execution for multi-level correlated queries

5.28.13

5.28.13.15

New features

Synced with upstream Greenplum Database 5.28.13

5.28.11

5.28.11.15

New features

Synced with upstream Greenplum Database 5.28.11

Bug fixes

Index scan in correlated subqueries produced incorrect results

5.28.9

5.28.9.14

New features

Synced with upstream Greenplum Database 5.28.9

Bug fixes

[5X backport] The elog function ignored multi-byte encoding when truncating long messages

[5X backport] The PartitionSelector mechanism did not return tuples in case of the type mismatch

5.28.7

5.28.7.13

New features

Synced with upstream Greenplum Database 5.28.7

Bug fixes

Fixed a broken URL in the ADB bundle service description

[5X backport] ORCA produced an incorrect plan for the `NOT IN` clause

5.28.6

5.28.6.11

New features

Synced with upstream Greenplum Database 5.28.6

Bug fixes

Fixed the `gpexpand` execution error that occurred for tables with dots in their names

Fixed the waiting queue corruption for resource groups

Fixed `SEGFAULT` that occurred during the table redistribution phase of the `gpexpand` operation

ADB Control known issues

Daria Barysheva

ADB CONTROL

To Table of Contents

Issue	From	Fixed	Workaround
Clusters that are connected to an external ADB Control instance should be upgraded along with the main cluster to ADB 6.29.0.3 in order for ADBM and ADB Control to work properly	4.14.2	—	Upgrade clusters to ADB 6.29.0.3

In AltLinux 8, the Docker engine update may break the *docker-compose* package, which causes the ADB Control start to fail	—	AltLinux fix	To fix */usr/lib/python3/site-packages/compose/service.py*, replace the following:
			`container.image_config['ContainerConfig'].get('Volumes') or {}`
			by:
			`container.image_config['Config'].get('Volumes') or {}`

The ***Reconfigure*** service action may fail for ADB Control hosted on CentOS in case of using external Query DB, since the CentOS repository does not have the required PostgreSQL version	4.13.0	—	Follow the steps: 1. Uninstall completely PostgreSQL 9 from the host with ADB Control. 2. Install PostgreSQL client of version 14 or higher. Do not install ADB Control on the ADB master host
After the ADB Control service is configured to use LDAP authentication with `FreeIPA` type, a list of groups is not loaded when you create a new mapping on the ***Users → LDAP group mapping*** page	4.0.0	—	Use basic authentication or LDAP with `MSAD` type (Microsoft Active Directory)
When a cluster is upgraded from 6.27.1.56 to 6.27.1.58, an error occurs if external ADB Control is used	4.10.3	4.10.3	Upgrade a cluster with ADB Control before upgrading clusters that use this ADB Control as external (in ***External ADB Control server parameters***)
After the transaction cancellation, plan nodes in the Plan & progress section will have the `executing` status and display the increasing execution time	4.8.8	4.9.1	Keep in mind that cancelled queries do not have executing processes
ADB Control 4.8.8 implements changes in API that affect communication between the main and external ADB Control services of different versions. When an ADB cluster with the main ADB Control is upgraded to 6.27.1.56.b1, clusters of older versions that use this ADB Control as external will not be able to perform ***Reconfigure***/***Start*** actions with the ADB Control service	4.8.8	4.8.8	In order to make all ADB Control service actions to work, upgrade clusters with the external ADB Control and versions older than 6.27.1.56.b1 to 6.27.1.56.b1
After ADB Control upgrade to 4.3.2, the `Export job` settings (that are defined on the ***Configuration → Job policy → Metrics offload*** page) are reset to defaults	4.3.2	4.3.2	Fill in and save the required settings. The problem does not affect future upgrades
Standby activation after switching from master fails on clusters with ADB Control/ADBM installed	4.3.1	4.3.2	Use external ADB Control/ADBM
In ADB Control 4.2.1, you cannot register new external ADB clusters with versions earlier than 6.23.3	4.2.1	4.2.1	Update ADB cluster to 6.23.3

Switching off sending metrics of inner queries to ADB Control may cause hangs of ADB queries	4.1.0	4.10.3	Turn on the GUC that enables sending metrics of inner queries in ADB Control or in ADB (as follows):
			`$ gpconfig -c adcc.monitor_inner_queries -v on`
			`$ gpstop -u`

Commands appear in the `Running` status on the ***Monitoring → Commands → Online*** page but after 14-16 seconds they freeze in the `Unknown` status (with no metrics updated). After the command completion, all metrics become available on the ***Monitoring → Commands → History*** page, but the `Unknown` status persists	4.1.0	4.2.0	1. Using `psql` or other SQL IDE, set the `adcc` user password via the following command: `ALTER USER adcc WITH ENCRYPTED PASSWORD '<password>';` 2. Open the ***Configuration → Clusters*** page in the ADCC UI and go to editing the cluster connection. 3. In the ***Password*** field, set the `<password>` value from step 1. Click ***Save***.

There is a potential memory leak with specific queries affected by the `gpperfmon` engine. If you use queries against huge tables with UDF that generate inner per-tuple queries, you may experience the significant RAM consumption, and even get OOM errors. The example is the `information_schema.columns` view, which can cause memory leak when being selected against a large system catalog	4.0.0	4.1.0	The possible solution is to switch off monitoring metrics (this operation requires cluster restart):
			1. Remove `gpadcc` from *shared_preload_libraries*, e.g.:
			`$ gpconfig -c shared_preload_libraries -v ""`
			2. Switch off the following parameters:
			`$ gpconfig -c gp_enable_gpperfmon -v off`
			`$ gpconfig -c adcc.explain_log_verbose -v off`
			`$ gpconfig -c adcc.explain_log_analyze -v off`
			3. Restart your cluster:
			`$ gpstop -a -M fast`
			`$ gpstart a`
			Remember that this workaround does not disable the ADCC UI and Arenadata DB Backup Manager

Backend ADCC server cannot connect to ADCC UI server. Data update may not always work on the details page	4.0.0	4.1.0	1. Connect to the ADCC server via SSH.
			2. Go to the */opt/adcc* directory.
			3. Edit the *docker-compose.yaml* file. For the *adcc_ui_server* and *adcc_backend_server* services, change the value of the `ADCC_EUREKA_CLIENT_PREFER_IP_ADDRESS` environment variable to `true`.
			4. Run the command and wait until all Docker containers stop:
			`$ docker-compose down`
			5. Run the following command:
			`$ docker-compose up -d`

It is impossible to configure the `Data cleanup` job on the ***Configuration*** page. In general, ADCC can work without data cleanup, but you need to monitor the metrics database size	4.0.0	4.1.0	1. Connect to the ADCC server via SSH.
			2. Go to the */opt/adcc* directory.
			3. Edit the *docker-compose.yaml* file. For the *adcc_scheduler* service, add the following environment variable: `ADCC_SCHEDULER_GRPC_PORT: 6572`.
			4. Run the command and wait until all Docker containers stop:
			`$ docker-compose down`
			5. Run the following command:
			`$ docker-compose up -d`

To Table of Contents

3.0.1

Date: 30.12.2020

Bug fixes

- Fixed UI scan down table reverse would be at date with single number of gateways

3.0.0

Date: 30.12.2020

New Features

- ADBM main upgrade to NET 7
- `updateAccount` updated to version 3.0

Bug Fixes

- Fixed an issue where the values were changed to `Number` when one were accessed
- Improving the field index IDs for **Returns** which were less obvious. ADB upgrades
- Updated missing UI configuration forms and other file formats

2.9.5

Date: 30.12.2020

New Features

- Fixed bug where the **Cleanup** action would delete valid configurations

Bug Fixes

- Fixed an issue where the **SCLEARDATE** was missing the **Partial Update** action

2.9.4

Date: 30.12.2020

Bug Fixes

- Fixed XML reference for backup was not working by the **Verify** action
- Fixed <gentle> and not displayed in the **Backup manager** page when still be stopped
- Fixed an issue during the open and close connection in the **Backup** action

Misc

- Changed the name of the event sending **Backup** and **Verify** instead of using UI proceedings

2.9.3

Date: 30.12.2020

Improvements

- Configuration is able to store information in use

Bug Fixes

- Storage service was checked only from files server, which could cause incorrect backup status acquisition

- Fixed issue bug, where all the **Close** type of the UI exception which causes rejecting. Now the UI has missing or single page which if the session engine to load the configuration

2.9.2

Date: 30.12.2020

Improvement

- Added a new option for the backup file, which using the **Verify** action
- Added a check of the ProgressBar backend availability during the table service

Bug Fixes

- Fixed missing data. For Reader, that were missing from the result
- Fixed the problem with the **Backup** action when the **Backup** action was executed
- Fixed the **Verify** action, which was not working with the **Backup** action
- Fixed **SUPPORTSSSL** issue that missing a long time to the end of the UI connection. Re-opening the **Partial Update** action
- Fixed the **Verify** action, which was not working with the **Backup** action
- Fixed the search for neighboring files. Now is when discovered during filtering XML
- Fixed filtering XML when a new connection is in the middle of the UI
- Fixed filtering XML when there is a configuration which was not found
- Fixed the method **SUPPORTSSSL** configuration would be starting at the beginning of the new file when filtering the XML
- Fixed the **Verify** and **Backup** action when filtering XML
- Fixed filtering XML when a new connection is in the middle of the UI
- Fixed filtering XML when there is a configuration which was not found
- Fixed the **Verify** and **Backup** action when filtering XML
- Fixed the **Verify** and **Backup** action when filtering XML
- Fixed a crash when the **Verify** action when filtering XML
- Fixed a crash when the **Verify** action when filtering XML

2.9.1

Date: 30.12.2020

Bug Fixes

- Added display XML in the **Partial Update** action
- Improving the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed **SUPPORTSSSL** issue that missing a long time to the end of the UI connection. Re-opening the **Partial Update** action
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the search for neighboring files. Now is when discovered during filtering XML
- Fixed filtering XML when a new connection is in the middle of the UI
- Fixed filtering XML when there is a configuration which was not found
- Fixed the **Verify** and **Backup** action when filtering XML
- Fixed a crash when the **Verify** action when filtering XML
- Fixed a crash when the **Verify** action when filtering XML

2.9.0

Date: 30.12.2020

New Features

- Configuration **ACTIVE** option, which **ACTIVE** is set to **true** if the **Partial Update** action is executed
- Configuration **ACTIVE** option, which **ACTIVE** is set to **true** if the **Partial Update** action is executed
- Implemented command line, the **primary part of service** action is executed for the **Partial Update** action
- Created the new action **Backup manager** and **Backup** action to manage and backup of the UI screen. Also, created a method of determining data
- Added the **Backup manager** and **Backup** action to manage and backup of the UI screen. Also, created a method of determining data
- In the ADBM report, improved performance of the UI screen

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.8.2

Date: 30.12.2020

Improvements

- Added the **Verify** action when the **Backup** action is used
- Added the **Verify** action when the **Backup** action is used
- Added the **Verify** action when the **Backup** action is used
- Added the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.8.1

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.8.0

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.7.2

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.7.1

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.7.0

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.6.6

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.6.5

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.6.4

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.6.3

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.6.2

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.6.1

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.6.0

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.5.5

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.5.4

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.5.3

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.5.2

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.5.1

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.5.0

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.4.0

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.3.2

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.3.1

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

2.3.0

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

1.7.3

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

1.7.2

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

1.7.1

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

1.7.0

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

1.6.3

Date: 30.12.2020

New Features

- Added new class for management of logging configurations
- Added several changes to the **Backup** action to support multiple UI instances (each UI with a limited backup) moving Operation Recovery ZIP) (see **Improvements**)

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

1.6.2

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

1.6.1

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Improvements

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup** action is used

Bug Fixes

- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used
- Fixed the **Verify** action when the **Backup** action is used

1.6.0

Date: 30.12.2020

New Features

- Added support for the **Verify** action when the **Backup** action is used
- Added support for the **Verify** action when the **Backup**

ADBM known issues

Daria Barysheva

ADB.M

To Table of Contents

Issue	From	Fixed	Workaround
ADBM agents with a version lower than 2.8.0 (compatible with ADB.6) cannot connect to the ADBM server 2.8.0	2.8.0	—	Use separate ADBM deployments for ADB 6 and ADB 7 clusters

If an NFS or CIFS storage used for backup becomes unavailable, the `pgbackrest` process can hang, making ADBM operations unresponsive. For example, a backup operation can remain in a hung state even after the *Protocol timeout* period (defined in the backup configuration) expires	—	—	1. Identify the `pgbackrest` process and check its state:
			`$ pprep -a pgbackrest`
			`$ ps -o pid,state,command -p <PID>`
			If the `state` parameter has the value of `D`, the process has entered an `Uninterruptible Sleep` state and cannot be terminated via a SIGKILL signal or `pgbackrest` timeouts until connectivity with the storage is restored.
			2. Mount your NFS or CIFS storage with the `soft` option, which allows system calls to return errors instead of waiting indefinitely. For example, add the following to the /etc/fstab file:
			▪ For NFS:
			`server:/share /mnt/share nfs soft,timeo=300,retrans=3 0 0`
			▪ For CIFS:
			`//server/share /mnt/share cifs soft,timeo=300,retrans=3,credentials=/path/to/credentials 0 0`

The *Audit* page does not show operations	2.6.5	—	In ADB Control → UI component parameters, set *Listening port* to `8890` for the main and external clusters. Run the *Reconfigure & Restart* action to apply changes
Clusters that are connected to external ADB Control should be upgraded along with the main cluster to ADB 6.29.0.3 in order for ADBM and ADB Control to work properly	2.6.5	—	Upgrade clusters to ADB 6.29.0.3
The standby's WAL directory is not recycled properly if `wal_sender_archiving_status_Interval` is greater than `0` and `archive_mode` is `always`, which causes data restore in ADBM to crash in some cases	2.0.4	—	Set `wal_sender_archiving_status_interval` to `0`
The backup repository configuration creation fails in ADBM CLI when the S3 plugin is used with default `uploadChunkSize` and `uploadConcurrency` settings	2.0.4	—	Configure `uploadChunkSize` and `uploadConcurrency` based on your system resources before creating a backup configuration. The S3 plugin will try to allocate the memory size equal to `segment_per_host` * `uploadChunkSize` * `uploadConcurrency`
The *Information → Backup manager* page does not display information for segment hosts in the `DOWN` status	1.0.0	—	This is the expected behavior that may be improved in future releases
Termination fails for streams with the *Restore mirrors* option set to `In parallel` (during the stream creation)	2.2.0	2.4.0	When creating streams with the `Streaming` restore type, set the `After primary` value for the *Restore mirrors* option
After upgrade to ADB 6.26.2, backups with the configuration created before upgrade fail	1.7.3	2.3.2	After upgrade, run the *Verify* action for clusters that have backup configurations

Restore fails if one of the cluster segment hosts is down for restore points created after the host was stopped	1.7.0	2.0.4	1. Edit the *ssh_config* file under `root` on the master host:
			`$ vi /etc/ssh/ssh_config`
			2. Add the following line to the end of the file:
			`ConnectTimeout 20`
			3. Restart the SSH daemon (`sshd`)
			`$ systemctl restart sshd`

The *Create Stream* modal window has the following restriction: the `Streaming` restore type is only a prototype, do not use it	1.3.1	1.7.3	Use only the *Copy* option for a stream
Mirrors are not restored automatically on a target cluster. If a target cluster already has mirrors, the restore job will fail, and if it doesn't then the restore job will finish without errors but the restored cluster will not have mirrors even if the source cluster had	1.3.1	1.3.3	DR cluster shouldn't have mirror segments
The *Create Stream* and *Restore* modal windows have the following restriction: the *Restore mirrors* option should not be used	1.3.1	1.3.3	Reset the *Restore mirrors* checkbox when setting up a stream or restore
The Disaster recovery copy action fails when: ▪ A source cluster doesn't have a standby and a target cluster has it ▪ A source cluster has a standby and a target cluster has not.	1.3.1	1.3.3	Standby should be present or absent on both source and target clusters
Restores list is empty for clusters with spaces in names	1.1.0	1.3.3	Cluster names shouldn't have spaces
Standby restore for a target cluster is not available	1.3.1	1.3.2	DR cluster shouldn't have standby master
It is impossible to restore data from a backup on the DR cluster when the source cluster number of data nodes differs from the DR cluster	1.3.1	1.3.2	DR cluster and source cluster should have the same topology
Cluster is marked `Down` in ADBM when master is on the same host as segment	1.3.1	1.3.2	Edit */opt/adbm-agent/service-configuration* and leave only one record for this host that describes ADBM agent roles: `ADBM_AGENT_ROLES=EXECUTOR,DISPATCHER`, then restart agent with the `systemctl restart adbm-agent` command
DR cluster cannot be used for writing	1.3.1	1.3.2	Do not use DDL or DML commands on DR cluster

DR cluster cannot be started after restoring	1.3.1	1.3.2	1. Backup *pg_hba.conf* of `-1` and `0` segments on DR cluster before running a restore stream. Save it to persistent storage (do not use */tmp*). Use the following commands (under the `gpadmin` user) on master host:
			`$ cp /data1/master/gpseg-1/pg_hba.conf /home/gpadmin`
			`$ gpssh -v -f /home/gpadmin/arenadata_configs/arenadata_segment_hosts.hosts -e 'cp /data1/primary/gpseg*/pg_hba.conf /home/gpadmin/'`
			2. Restore *pg_hba.conf* after completing *Disaster recovery copy stream* action via the following commands (under the `gpadmin` user) on master host:
			`$ cp /home/gpadmin/pg_hba.conf /data1/master/gpseg-1/`
			`$ gpssh -v -f /home/gpadmin/arenadata_configs/arenadata_segment_hosts.hosts -e 'find /data1/primary/gpseg* -maxdepth 0 -exec cp /home/gpadmin/pg_hba.conf {} \;'`
			3. Change the `synchronous_standby_names` parameter on all primary segments from `'*'` to `''` in */<data_directory>/primary/gpseg*/postgresql.auto.conf*.

The *Create Stream* and *Restore* modal windows have the following restriction: choosing particular databases from the *Database* list will cause the job to fail, do not use it	1.3.1	1.3.2	Select all databases when setting up a stream or restore
It is impossible to add external ADB clusters to the general-purpose ADBM from the ADBM UI	1.0.0	1.3.1	1. Ensure the external ADB cluster with the installed ADBM service exists in ADCM. 2. Connect to the Linux console. Generate the Basic Authorization hash with base64 for a user with access to Arenadata DB Backup Manager via the following command: `echo -n <adbm_user>:<adbm_user_password> | base64`. For example: `$ echo -n adbm_user:Password | base64` Result: `YWRlbV91c2VyOlBhc3N3b3Jk` 3. Send the following POST request to the general-purpose ADBM host: ▪ Header parameters: • `Accept` • `Accept-Charset` • `Authorization`: It should have the value started with `Basic ` and then the base64 value from step 2. • `Content-Type` • `X-ADBM-USER`: It should have the `adbm_user` value from step 2. ▪ Body: `{ "clusterName": "<name of external ADB cluster in ADCM>", "clusterType": "<purpose of ADB cluster>", "clusterVersion": "<version of ADB cluster>" }` The following is an example of the POST request with the Linux `curl` command: `$ curl --request POST \ --url http://adbm-main:8890/backend/adbm/api/v1/clusters \ --header 'Accept: application/json' \ --header 'Accept-Charset: ISO-8859-1' \ --header 'Authorization: Basic YWRlbV91c2VyOlBhc3N3b3Jk' \ --header 'Content-Type: application/json' \ --header 'X-ADBM-USER: adbm_user' \ --data '{ "clusterName": "adb-demo", "clusterType": "ADB demo stand", "clusterVersion": "6.22"}'` A successful response contains a JSON with the generated identifier of an external cluster in ADBM. The cluster becomes visible in *Arenadata DB Backup Manager → Clusters* with the `Down` status. 4. In ADCM, go to the external ADB cluster and select *Services → ADBM → Configuration*. 5. Set the *Show advanced* flag and edit the ADBM agent service configuration parameter `ADBM_EUREKA_CLIENT_SERV_URL_DEF_ZONE` located in the bottom area. Replace its value with URL of the service registry for a general-purpose ADBM host, e.g. `http://adbm-main:8761/eureka`. 6. Apply the *Reconfigure & Restart* action to ADBM. Upon success, the cluster status in *Arenadata DB Backup Manager → Clusters* is changed to `Up`.
FQDN names in the `hostname` and `address` columns in the `gp_segment_configuration` table are not supported. Essentially, it is a blocker for ADBM utilizing in clusters where FQDNs are used	1.0.0	1.1.0	Modify names in the `gp_segment_configuration` table to short ones. Take into account that it is an extremely dangerous operation, which can harm a cluster
Segment servers have an additional role that they don't need to have. ADBM will work, but with extra queries on segment servers. Users can discover it only from a log	1.0.0	1.1.0	Change a configuration file on the *ADCM → ADBM → Configuration* page: 1. Set the *Show advanced* flag. 2. Find the *ADBM agent service config parameters* field. 3. Replace `master` by `adb.master` and `segment` by `adb.segment`. 4. Click *Save* and then run the *Reconfigure & Restart* action.
